recent preparation which you may know Casumen
lish preparation of very pure soluble casein. What is
ay of them? I think that one may say that they are
t the most useful of all the artificial foods which have
troduced. There is no doubt that these preparations
added in very large amount to ordinary foods such as
and milk and even to some solid foods with great
t and without the patient being aware of the addition
seeing that these preparations contain 80 or 90 per cent.
ro proteid you can understand that the amount of
ive material which they are the means of supplying is
lderable. I know of no special indications necessitating
use but there are many conditions of disease where one
to enrich a fluid diet. If a patient is on pure milk
you want to increase the nutritive value of the milk
t is that such preparations can be made very useful
you can add them knowing that they will be easily
ted and be almost completely absorbed and that they can
patient no harm. Looking at the subject all round these
amongst the most useful of all the artificial foods and
the further advantage that, as most artificial foods go
are cheap because the casein is extracted from skim
which would otherwise be thrown away and the
tion can therefore be produced at a low cost.
third class in this group are those derived from
able sources These were introduced because people
ted to get a cheaper source of proteid animal sources
necessarily expensive The one which has been
recommended is Aleurone which is the proteid of
It is colourless, odourless tasteless, and fairly
But for some reason or other it has never properly
aught on.
The last class in the group are those containing sub-
nces derived from both animal and vegetable sources
best example of these is Tropon which is relatively
ely cheap, because it is derived from waste animal and
table substances. It was found that by wa hing away
fat from these substances a powder could be obtained
ich was practically free from odour and taste which could
kept indefinitely and which was also rich in proteid It
advertised considerably in this country but has not come
large use. It has the disadvantages of not being
lly soluble and of having a rather sandy taste.
The next sub-group includes those foods which are intended
supply especially carbohydrates. The best example are
malt extracts The e contain roughly the following pro-
ose sugar from 50 to 55 per cent., soluble starch
10 to 15 per cent. proteids, from 5 to 6 per cent. and
from 1 to 2 per cent. I want to consider for a moment
t the value of malt extracts is because they are, perhaps,
largely prescribed than any other patent food They
originally made becau e they contained diastase being
pared by evaporating down an infusion of malted barley
low temperature so that the ferment is not destroyed by
t, and it was hoped that they would help the digestion
other starchy foods by converting them into sugar
consequence of this view is that malt extracts are
essarily expensive as they have to be produced very care-
ly, in case the diastase should be destroyed. When
prescribe malt extract do you ever ask yourselves
at it is you particularly want to do? I put that question
ause I want to ascertain for my own information whether
majority of people who order malt extract have any
of diastase at all. When you order it are you
of giving your patient diastase to help him to
e rest of his starchy food? Or do you order it for
sugar and proteid matter which it contains? I hope in
d ussion which is to follow that I shall get some
rmation on this point. If the medical profession were
ay that they only wanted malt extract for the sake of its
ar then the cost of its manufacture might be reduced
cent. I think that the majority who prescribe it do
because they want sugar But what is the value of malt
ract regarded as a source of sugar? These preparations
tain only half the weight of sugar that ordinary loaf
contains. You may say that malt extracts contain
sugar but there is no proof that malt sugar is much
erior to other natural sugars. It is true that it is
digested and it certainly seems to agree better
the stomach than cane sugar But such a substance as
contains wholly digested sugar ready to be absorbed
into the blood and honey contains a larger
of dextrose than does anything else I know of
[illegible] 2s 9d, a pound of malt extract costs

3s and the honey is the better source of sugar of the two Therefore if one does not want to get diastase one is acti[illegible] more wisely by ordering honey But of course, the patie[illegible] might laugh at you if you ordered honey whilst he would swallow any quantity of malt extract costing double the price. I would put in a word here for milk sugar or lactose which is one of the best methods of enriching a diet in carbohydrates Lactose does not taste sweet and it is a food It can be added largely to liquid foods without making them unpleasantly sweet You can stir the lactose into milk and thus increase its food value without adding to its bulk Certainly I think it deserves a better place among sick room requisites than it holds.

We now pass to the third sub-group—those which are intended to supply us with fat. The most important of those is cod liver oil emulsion Here again one is met by the same question as in considering the malt extracts Why does one order cod liver oil emulsion? Wherein does the virtue consist? Is it for any particular virtue in the emulsion or is it merely for the fat? I do not know that cod liver oil fat posses es any special virtues. You believe it to be specially easy of digestion? But in cream you get a more valuable substance because ordinary cream contains more than 50 per cent. of fat, and butter fat is as easily digested and ab orbed as the fat of cod liver oil besides having the advantage of being much more palatable and considerably cheaper So I do not see any reason for ordering cod liver oil emulsion if you only want an easily digested fat when there are such substances as ordinary cream and butter procurable. I have also put down in this category petroleum emulsion because it is so largely advertised and because it is in a sense, one of the most delusive of all these artificial preparations It is certainly believed by many people to be a substitute for cod liver oil A mineral oil like petroleum can never by any chance, be absorbed into the blood, and any action of petroleum emulsion is purely local and it cannot feed any more than vaseline which you rub into the skin I took the trouble some time ago to demonstrate that by analysing the fæces of a person who was taking petroleum emulsion I was able to recover every gramme from the stools, not one single particle of it got near the blood Even if it did the body could not utili e it because it is a hydrocarbon and not a fat

Pancreatic emulsion is a fairly well known preparation and is rather pleasant to taste. It is really emulsified lard flavoured with clove oil. It keeps very well and it is quite easy to take. But it does not contain more fat than butter which contains 80 per cent. and lard is certainly not more digestible than is butter fat. As long as there is butter in the universe, therefore, I cannot see any excuse except a psychological one, for manufacturing pancreatic emulsion.

Then we come to the fourth subdivision of the first great group the mixed fatty and carbohydrate foods. One of these is Virol and another which has been recently introduced is Virvis. These are preparations containing essentially malt extract and marrow fat flavoured with lemon juice Of course such a preparation has a considerable amount of nutritive value. Virol contains 20 per cent. of fat and 60 per cent of carbohydrate and two ounces of it cost 9d Virvis is rather cheaper but I have not analysed its constituents. But here again you will see that there is no great virtue in those preparations they contain a certain amount of fat and carbohydrate so does chocolate, chocolate contains more fat and more carbohydrate while ordinary toffee, Everton toffee, consists of equal quantities of fat and carbohydrate without any water So I cannot see any use for the existenc[illegible] of those things so long as you can prescribe chocolate an[illegible] Everton toffee—except, of course a psychological advantag[illegible] I shall deal briefly with the beef extracts

I pass next to the beef extracts I shall deal briefly wit[illegible] these because you have all the essential facts in the analyse[illegible] which I have put before you in Table I Beef extracts i[illegible] the ordinary sense of the term, are of very little, if an[illegible] food value. They contain hardly any proteid, what they chiefly contain are the extractives and mineral matters Experiment has shown that the extractives are only o[illegible] use in so far as they stimulate the appetite they have no other action whatever they are not foods, they are not true stimulants and they have no particular influence in the body except that of increasing the appetite for other food So the place for them is in the kitchen and not in the sick room. That was fully recognised by Liebig and was only lost sight of by his successors. But then there came people who tried to make meat extracts of food value. They added to the ext[illegible] fibre—a [illegible] for example in the case of [illegible] so long as the sputum remains moist the surrounding atmosphere is not impregnated with the poison (tubercle bacilli or its spores), but if the sputum is allowed to dry and become pulverised the atmosphere may readily become impregnated with the poison. On this point Dr James B Russell states —

> In order to be air borne the sputum must be dried and broken up into dust If discharged into a handkerchief it speedily dries especially if it is put into the pocket or beneath the pillow In the last stages of consumption the patient becomes weak the sputum is expelled imperfectly, pillows sheets, and handkerchiefs are soiled If a male the beard or moustache is smeared Even in the hands of the cleanly, without special precautions such circumstances all tend to the production around the patient of a halo of infected dust maintained by every process of bed making or of cleaning which includes the pernicious process happily described as 'dusting In the hands of the careless and the dirty the infectivity is of course, greatly aggravated It attains its maximum of intensity where the filthy habit of spitting on the floor prevails, especially if carpeted

The process of drying does not (immediately) destroy the vitality of the tubercle bacillus and its spores Consequently, dust derived from the dried sputum of a case of phthisis is for a time at least infective, but so far as I know the maximum length of time which the tubercle bacilli and their spores may retain their vitality has not as yet been definitely determined Dust containing the tubercle bacillus and its spores may certainly remain infective for several weeks, probably, under conditions which are favourable for the retention of their vitality, for several months, and possibly for some years.[5] I say under conditions which are favourable for the retention of their vitality, and the most important seem to be the presence of dirt and the absence of fresh air and of sunlight. On the other hand, there seems every reason to suppose that under conditions which are unfavourable for the retention of their vitality (cleanliness, plenty of fresh air, and of sunlight) the tubercle bacillus and its spores quickly die On this point Professor G. Sims Woodhead makes the following very important statement —

> The tubercle bacillus may, under certain conditions, remain and grow in wall paper and even in certain soils though this as yet has not been fully proved but we may take it for granted that outside the animal body the conditions of nutrition and of general temperature are so unfavourable these unfavourable conditions are so helped by sunlight by desiccation, by oxidation and the numerous other influences that interfere with the growth of micro-organisms (especially those that have a distinct parasitic existence), that if we could cut off the supply coming from patients both human and brute, the danger from infection would soon be reduced practically to the vanishing point [6]

It seems certain that the dust derived from the dried sputum of cases of phthisis is the chief means by which the tubercle bacillus is conveyed from human beings affected with phthisis to other healthy human beings The number of tubercle bacilli which are given off in the sputum of a patient affected with phthisis in the course of 24 hours is enormous, and when it is remembered that patients with phthisis continue to expectorate and to give off countless numbers of tubercle bacilli, not only for weeks but for months and, in some cases, for years, the magnitude of this source of infection will be at once realised. On this point Professor William Osler says —

> Patients with advanced pulmonary tuberculosis throw off in the expectoration countless millions of the bacilli daily Some idea of the extraordinary numbers may be gained from the studies of Nuttall From a patient with moderately advanced disease the amount of whose expectoration was from 70 to 130 cubic centimetres daily he estimated by his method that there were in 16 counts, between Jan 10th and March 1st from one and a half to four and a third billions of bacilli thrown off in the 24 hours These figures emphasise the danger associated with phthisical sputa unless most carefully dealt with When expectorated and allowed to dry the sputum rapidly becomes dust and is distributed far and wide. The observations made by Cornet under Koch's supervision are in this connexion most instructive He collected the dust from the walls and bedsteads of various localities and determined its virulence or innocuousness by inoculation into susceptible animals Material was gathered from 21 wards of seven hospitals three asylums two prisons from the surroundings of 62 phthisical patients in private practice and from 29 other localities in which tuberculous patients were only transient frequenters (out patient departments streets, &c.) Of 118 dust samples from hospital wards or the rooms of phthisical patients 40 were infective and produced tuberculosis Negative results were obtained with the 29 dust samples from the localities occasionally occupied by consumptives Virulent bacilli were obtained from the dust of the walls of 15 out of 21 medical wards It is interesting to note that in two wards with many phthisical patients the results were negative indicating that the dust in such regions is not necessarily infective The infectiousness of the dust of the medical and surgical divisions of a hospital is in the proportion of 76 6 to 12 5. In a room in which a tuberculous woman had lived the dust from the wall in the neighbourhood of the bed was infective six weeks after her death No bacilli were found in the dust of an inhalation-chamber for consumptives The experiments of Strauss at the Charite Hospital, Paris, are important In the nostrils of 29 assistants, nurses and ward tenders he placed plugs of cotton wool to collect the dust of the wards In nine of the 29 cases these contained tubercle bacilli and proved to infective animals [7]

In some cases of tuberculous disease, including some cases of phthisis, in which the intestine is affected with tuberculous ulceration, tubercle bacilli are given off from the bowels—i.e, in the fæces But this is a much less frequent and important source of infection than the sputum of phthisis Primary tuberculous disease of the intestine is extremely rare, tuberculous ulceration of the intestine chiefly occurs in acute cases of phthisis with rapidly disseminated tuberculous lesions and in the later stages of chronic cases Tubercle bacilli may also be given off from the bodies of human beings affected with tubercle in other ways, as, for example, in the urine in which the genito-urinary tract is affected with tubercle, but tuberculous disease of the genito-urinary tract is comparatively rarely developed in cases of phthisis, and primary tuberculous disease of the genito urinary tract is, in comparison with phthisis, a very rare condition Consequently in comparison with the sputum of phthisis this is an unimportant source of infection Discharges from abscesses connected with tuberculous glands, bones, joints, &c, may also be a source of infection but in comparison with the sputum of phthisis this is a very insignificant one Such discharges contain, in comparison with the sputum of phthisical patients, few tubercle bacilli, *the material from scrofulous* joints and bone tuberculosis appears to be less virulent than that from other varieties of human tuberculosis, and further since cases of this kind usually come under the care of the surgeon at a comparatively early stage of their development and are consequently subjected to careful antiseptic treatment, this source of infection as a direct cause of phthisis and other tuberculous affections may for practical purposes be entirely, or almost entirely, ignored. Tuberculous affections of the skin (lupus, tuberculous ulcerations) need not, for practical purposes, be taken into account In such ulcerative lesions of the skin the tubercle bacillus is present in very sparse quantities and the discharges from such ulcerations may for practical purposes be ignored as a source of infection

To sum up, tuberculous disease is conveyed from one human being to another by means of the secretions, excretions, and discharges which contain the tubercle bacillus or its spores, these discharges, more especially the sputum of phthisical patients, become dried and pulverised and are inhaled in the form of dust with the inspired air. The sputum of phthisis is by far the most important source of infection by which the tubercle bacillus is conveyed from one human being to another

6 Further, if dust which contains the tubercle bacillus is capable of producing phthisis and other forms of tuberculous disease when introduced into the bodies of unaffected and susceptible persons, it follows that susceptible persons who inhabit the rooms and houses in which dust which is impregnated with the tubercle bacillus is allowed to remain and to accumulate run some risk of being affected I say susceptible persons, for, as I will presently point out, the risk which absolutely healthy persons run from inhaling the tubercle bacillus or its spores seems to be, comparatively speaking, small. It is certain that the contagious material (the dust which contains the tubercle bacillus or its spores), unless great attention is paid to cleanliness and disinfection, is apt to retain its vitality in particular houses and rooms (the houses and rooms in which patients affected with phthisis have lived and died) for considerable periods of time and that such houses and rooms are apt to be centres of infection Dr Arthur Ransome and others have recorded cases which leave no manner of doubt on this point

7 Tuberculous disease in the human subject may also be due to the introduction into the body of the tubercle bacillus or its spores derived from the lower animals, and especially from bovines, affected with tubercle, in other words, tuberculous disease in the human subject may be due to the introduction into the gastro intestinal tract of tuberculous milk or tuberculous meat Two Royal Commissions have recently considered and reported on the question of tuberculosis in its

---

[5] A case recently came under my notice in which there seemed reason to suppose that tubercle bacilli or their spores had retained their vitality in a certain room for four years

[6] Edinburgh Medical Journal May, 1899 p 467

[7] Principles and Practice of Medicine, third edition, p 261

to food and milk In the report of the last Com the following statement occurs —

> have had before us the unanimous finding of the Royal Com on Tuberculosis, which reported in 1895 to the effect that disease in bovine and other animals is identical with that the human subject and that it is communicable from one to the though the manifestation of the disease differs in some respects the human subject from that in the lower animals. We have also red their finding that "any person who takes tuberculous matter to the body as food incurs risk of acquiring tuberculous disease." that has come before us in the course of our inquiry has raised doubt in our minds as to the accuracy of this opinion At the time we think that there has been a tendency in some minds to erate the extent of the risk arising from meat.

Milk.—Almost all authorities are agreed that tuberculous lk is a frequent and most important cause of tuberculous sease in the human subject Butter made from tuberculous milk is also infective And in this connexion it is to note that while the mortality from tuberculous eases of all forms, and especially from phthisis has been ormously reduced of recent years the mortality from tabes which is by far the most frequent form of tuberculous disease in children and which seems to be chiefly due infection by tuberculous milk does not seem to have gone any noteworthy diminution during the very of sanitary progress which has been associated with substantial diminution of death from tuberculous affec- at all ages in England and Wales and that this result coincided in point of time with a large increase in the onsumption of milk. The full statement of the Royal on on this point is as follows —

> We note therefore, with satisfaction that death from tuberculous ease in all its forms and at all ages has steadily fallen from 483 per million during 1851-60 to 2122 during 1891-95—a diminu- of 39·1 per cent—and also that at every age period for statistics are available there has likewise been a decrease, nes of a very substantial character Further taking the age of 15-45 years as the period of life when meat forms a very prominent article of food and dividing that term into five-yearly or 10 yearly periods, we find that the diminution of death from tuberculous disease has ranged from 62·8 per cent. at the age-period 15-20 years to 30·8 per cent at the age-period 35-45 years In recording this enormous reduction in the amount of death from this cause we must recall the fact that during this age period phthisis is the form of registered death which altogether overwhelms all other forms of fatal tuberculous affections and that phthisis may be considered as due to the reception of tuberculous infection rather by the respiratory than by the digestive tract. For the age-period 0-5 years there has also been a reduction in death from tuberculous disease in all forms from 6764 per million living at that age in 1851-60 to 4155 in 1891-95—a diminution of 27·8 per cent. This reduction is, however but little more than half that which has taken place at the age-periods 15-20 and 20-25 years; and when we come to examine that form of tuberculous disease—namely tabes mesenterica—which is believed to be mainly due to infection received by the digestive tract we find that whilst at the age-period 0-5 years, when milk forms so important an article of diet, the rate of death per million living has shown first increase then decrease, yet the rate which stood at 1625 during 1851-60 had only fallen to 1577 for the period 1891 95 a diminution of but 3·0 per cent. In this connexion we feel it necessary to recall the fact that the term tabes mesenterica as used in our death records is very indefinite and that it has comprised and doubtless still comprises a considerable amount of death from certain diarrhoeal affections which are not really tuberculous. But whilst this is so it must also be remembered that the rate of mortality from tabes mesenterica which more than any other represents tuberculosis in infancy has signally failed to undergo any noteworthy diminution during the very period of sanitary progress which has been associated with such substantial diminution of death from tuberculous affections at all ages in England and Wales and that this result has coincided in point of time with a large increase in the consumption of milk.

Although authorities are not absolutely agreed upon this point the weight of evidence seems strongly in favour of the view that the milk of a cow affected with tubercle only becomes tuberculous—i.e. contains the tubercle bacillus or spores—when the milk producing apparatus (mammary glands, milk ducts and udders) is itself affected with local tuberculous disease. In other words, the great majority of authorities are agreed that the mere presence of tuberculous disease of the internal organs is not attended with the presence of the tubercle bacillus or its spores in the milk. On this point the Royal Commission states —

> Considerable difference of opinion exists among experts as to the extent to which a cow may be affected with tuberculosis without rendering her milk dangerous. It was not proved to our satisfaction that tubercle bacilli had ever been detected in milk unless drawn from a cow with tuberculosis of the mammary gland

Dr Sidney Martin's observations and opinions on this point are very definite. He concludes that —

> When tuberculosis of the cow affects only the internal organs and not the udder the milk is not infective but that in all cases where the udder is tuberculous the milk becomes infective and is indeed often extremely virulent. Moreover, the butter butter-milk and skimmed milk obtained from this class of milk is also extremely infective There is no question, therefore, that this class of milk ought not to be used as food and it is certain that its exclusion would lead to a great diminution in the large number of cases of tuberculosis that occur in children

Infection by tuberculous milk is a most important source of tuberculous disease, more particularly of the mesenteric glands, and therefore of generalised tuberculosis and secondary tuberculous lesions in other organs and tissues, and consequently in the lungs—i.e. of secondary phthisis Infection by tuberculous milk seems chiefly to occur in children and is so far as we know comparatively speaking rare in adults It is possible, however, as Dr James Niven has suggested that adults are more frequently infected through it than is usually supposed.*

With regard to the frequency with which infants and children are affected with tuberculosis and the frequency with which children are infected through tuberculous milk the following statement from the report of the British Medical Association on tuberculosis is of importance —

> Experience has further shown that infants and children dying of respiratory and wasting diseases are in a large proportion affected by tuberculosis although the patients have not presented obvious symptoms of the disease during life The mortality from tuberculosis in early childhood is not decreasing as it is at other ages in the United Kingdom and the opinion that this great prevalence of the disease in infancy and childhood is due to infection through the alimentary canal by milk from tuberculous cows appears to be well founded The following table, showing the mean death-rates from tabes mesenterica in England and Wales among infants under one year of age per million living is given by Sir Richard Thorne Thorne in his second Harben Lecture :—

1851-60	3160	1881-85	4356
1861 70	3900	1886-90	4462
1871-80	4467	1891-95	4046*

I do not, of course mean to imply that in all cases in which tubercle has its starting point in the mesenteric glands or gastro-intestinal tract the disease is due to tuberculous milk. There is every reason to believe that in some perhaps a considerable proportion of cases the tubercle bacillus and its spores are inhaled with the inspired air and then swallowed, and in the great majority of cases in which the infection is introduced into the body in this way the poison (tubercle bacillus) is derived from cases of phthisis. It has also been suggested that tubercle may be communicated to a healthy child by kissing (the tuberculous sputum from the mouth of the affected person getting on to the lips and thence into the alimentary canal of the non affected person), through the milk of a tuberculous mother or nurse (this must be exceedingly rare for in the human subject the mammary gland and nipple are very rarely indeed affected with tubercle), by a tuberculous dog or cat licking the face of a healthy child, &c But every experienced and judicially minded observer who takes an unprejudiced view of the question will I think, allow that such methods of propagation with perhaps the exception of kissing (for it is not improbable that this is a more frequent mode of infection than is generally supposed) are so extremely infrequent and so exceptional—I would even venture to say so fanciful—that they may for practical purposes be entirely ignored In short it cannot, I think, be doubted that the tubercle bacillus is very frequently introduced into the bodies of children through the gastro-intestinal tract by means of tuberculous milk. Against this view it has been argued that milk cannot be such a potent channel of infection as is usually supposed, since tabes mesenterica and other forms of tubercle are more common in the poor than in the rich and since the children of the poor drink much less milk than the children of the rich. But this argument does not carry conviction to my mind. In my opinion the reasons why tabes mesenterica and other forms of tuberculous disease more frequently result in the children of the poor than in the children of the rich from the ingestion of tuberculous milk are—(1) that in the children of the poor the gastro-intestinal tract and mesenteric glands are so much more frequently in an unhealthy condition (the gastro-intestinal tract is in a condition to absorb the tubercle bacillus or the mesenteric glands are in a condition to form a suitable nidus for its development) and (2) that in consequence of lowered vitality (due to insufficient food insanitary surroundings &c.) the resisting power—the vital resistance as it has been termed—of the poor child against the tubercle bacillus is less than the resisting power of the rich and well cared-for child

---

* Manchester Medical Chronicle vol. vii 1897 p. 8.

* British Medical Association; Report on Tuberculosis Jan. 18th 1899

That a large amount of tuberculous disease in the human subject, and especially in young children, is due to the drinking of tuberculous milk seems to be shown, as has already been pointed out, by the facts (1) that while the death rate from all forms of tuberculous disease and especially from phthisis during the age-period from birth to five years—the milk drinking age *par excellence*—has during the 45 years from 1851 to 1895 markedly diminished (the diminution from all forms of tuberculous disease being 29·9 per cent and the diminution from phthisis being 66 per cent.), the death rate from tabes mesenterica has during the same age-period diminished only 3 per cent., and below one year of age the mortality from tabes mesenterica has during the same period of time (1851 to 1895) apparently increased by no less than 27·7 per cent.,[10] and (2) that during this period (from 1851 to 1895) there has been a very large increase in the consumption of milk.[11]

Tuberculous meat —Tuberculous meat is probably also an occasional but, so far as is known, by no means a frequent, cause of tubercle in the human subject. On this point the Royal Commissioners state —

> At the same time we think there has been a tendency in some minds to exaggerate the extent of the risk arising from meat When some years ago tuberculosis in human beings and other animals was first proved to be interchangeable we think that an exaggerated view was taken of the extent of the danger arising from meat, and that this view is still acted on in certain places

Highly tuberculous meat is rarely sold for human food and rarely eaten, for a marked degree of tuberculosis in meat is readily perceived by the naked eye Further, thorough cooking destroys the vitality of the tubercle bacillus, hence, mere surface contamination of the (sound) flesh of a tuberculous animal, such as may be produced by the knife of the butcher in dressing the carcass, is not likely to lead to the production of tuberculosis in the human subject, at all events in this country It is very different in the case of milk The tuberculous character of milk can only be recognised by the skilled observer—i e, after bacteriological examination or after cultivation or inoculation experiments Further, milk is usually consumed in the uncooked state Again, it must be remembered that milk is an admirable nidus for the development of micro organisms Hence, when milk is tuberculous the dose of the poison (the tubercle bacillus) is apt to be a large one and the intensity of the poison (owing to the high state of vitality of the bacilli) is often very great

That comparatively little tuberculous disease in the human subject is due to eating tuberculous meat seems shown by the facts "(1) That during the 45 years (from 1851 to 1895) the diminution of the death rate from all forms of tuberculous disease during the age period from 15 to 45—*the meat eating age as it may be termed*—has been 45 per cent. and the diminution in the death rate from phthisis has been 48 per cent, and (2) that during this same period of time (1851 to 1895) there has been in this country an enormous increase in the amount of meat consumed."[12]

So far as is at present known tuberculous disease is almost exclusively conveyed from the lower animals to the human subject through the medium of tuberculous milk or tuberculous meat (the flesh of tuberculous cows or pigs) In both cases the tubercle bacilli or their spores are introduced into the alimentary canal of the human subject. It seems probable that the tubercle bacilli introduced in this way usually first produce (local) tuberculous disease in the mesenteric glands, and subsequently after becoming diffused, (secondary) tuberculous disease of the lungs and other organs It is, however, highly probable that in some cases in which tubercle bacilli are introduced into the gastro intestinal tract they are carried by the blood to the lungs or other tissues (cerebral membranes, for example), where they produce primary tuberculous lesions—i e, without first producing local tuberculous disease in the intestinal or mesenteric glands In this connexion I would direct attention to the following statement of Dr Sidney Martin—viz "It must be granted, from the experiments in pigs which have been recorded, that it (milk) may also be a source of tuberculous (scrofulous) glands in the neck."[13]

8 The chief sources of tubercle in the human subject are (1) the sputum of human beings affected with phthisis, and (2) the milk of cows affected with local tuberculous disease of the milk producing apparatus (udders, &c)

9 Primary tuberculous disease of the lungs *seems* to be comparatively rarely due to infection by tuberculous milk or tuberculous meat. It is probable that when children are affected with phthisis the tuberculous lung affection is either produced in the ordinary way (the tubercle bacillus being inhaled and introduced into the respiratory tract or, after alighting on the pharynx, into the gastro intestinal tract) or that the phthisis is secondary to tuberculous disease of the mesenteric glands Primary phthisis appears to be, comparatively speaking, rare in infancy and childhood Though phthisis may occur at any age it chiefly occurs during active adult life, the greatest number of deaths occurring between the ages of 35 and 45 years It has been suggested that the disease is over looked in children owing to the fact that children do not expectorate. But this explanation cannot be accepted, for it is an actual fact, definitely proved by post-mortem observation, that phthisis (I mean the condition which we clinically term phthisis, I exclude miliary tuberculosis of the lungs without cavity formation) is very rarely met with in children compared with its frequency in the adult The reason seems to be that the resisting power of the lung of the child is greater than the resisting power of the lung of the adult, or, as Sir Hugh Beevor puts it, "It is the power of the lung to resist infection which determines the curve of the phthisis rate at early ages "[14]

10 The channels through which the tubercle bacillus or its spores are introduced into the human subject The tubercle bacillus or its spores may be introduced into the human subject either (1) with the inspired air, (2) with food or drink, or (3) by means of inoculation.

Infection through the inspired air —When the tubercle bacillus or its spores are introduced with the inspired air the poison is in the great majority of cases derived from the dried sputum of cases of phthisis, though other discharges which contain the tubercle bacillus or its spores and which become dry and pulverised, may, of course, be the source of the poison When the tubercle bacillus or its spores are inhaled in the inspired air, the poison may pass into the respiratory passages and may alight on the larynx, bronchial mucous membrane, or possibly the terminal air cells of the lung, or it may alight on the nasal mucous membrane, tonsils, or pharynx. Absorption from the tonsils and throat is probably a frequent cause of tuberculous disease, more particularly of tuberculous (scrofulous) disease of the cervical glands Tubercle bacilli which are inhaled with the inspired air may, instead of passing into the respiratory tract, be swallowed and be absorbed from the gastro-intestinal tract, producing tuberculous disease of the mesenteric glands, &c.

Infection through the gastro intestinal tract —The frequency with which tabes mesenterica and other forms of tuberculosis seem to be produced in children through the introduction of tuberculous milk into the gastro intestinal canal has already been pointed out. Possibly tuberculous disease in the adult is more frequently due to tuberculous milk than is usually supposed

Infection by means of inoculation.—In man inoculation seems very rarely to produce internal tuberculosis When tubercle is induced in this way it usually remains local The warty affection which occasionally occurs on the hands of the pathologist has been proved to be a local form of tuberculosis Butchers occasionally contract the same form of (local) tubercle from dressing diseased (tuberculous) carcasses. In cases of primary phthisis the poison seems, in the great majority of cases, to be introduced into some part of the respiratory tract with the inspired air—air which contains the tubercle bacillus or its spores.

ADDENDUM. PROFESSOR KOCH'S VIEWS REGARDING BOVINE AND HUMAN TUBERCULOSIS.

In his address at the British Congress on Tuberculosis

---

[10] Absolute reliance cannot I think be placed on these figures I do not mean to imply that they do not accurately represent the exact numbers and causes of death as registered They *of course do so* But exactness of diagnosis and classification have without doubt varied during the past 45 years Hence we cannot be at all certain that cases which are now classed as tabes mesenterica were so classed 45 years ago and *vice versa* Further as the last Royal Commission on Tuberculosis points out the term *tabes mesenterica* is used in a very loose way Many cases of diarrhœa in children are classed as tabes mesenterica but in true tabes mesenterica (tuberculous disease of the mesenteric glands) diarrhœa is often absent for in the great majority of cases of tabes mesenterica there is no tuberculous ulceration of the intestine

[14] THE LANCET, April 15th, 1899, p 1066

(July 23rd, 1901) Professor Koch made the following statement Though the important question whether *man is* insusceptible to bovine tuberculosis at all is not yet absolutely decided and will not admit of absolute decision to-day or to-morrow one is nevertheless at liberty to say that if such a susceptibility really exists the infection of human beings is but a very rare occurrence. I should estimate the extent of infection by milk and flesh of tuberculous cattle and the butter made of their milk as hardly greater than that of hereditary transmission and I therefore do not deem it advisable to take any measures against it Professor Koch based this remarkable opinion (1) upon the belief, founded on experiment and observation that human and bovine tuberculosis are not identical (2) upon a series of experiments which seemed to show that human tuberculosis is not *communicable to cattle and (3) upon the* fact that primary tuberculosis (tuberculous ulceration &c.) of the intestinal tract is extremely rare in man He consequently concluded that bovine tuberculosis is very rarely if ever communicated to man by means of tuberculous milk and tuberculous meat. These conclusions *and the data on* which they are founded have not as yet been accepted by the *profession.*

Many leading authorities maintain that human tuberculosis *is communicable* to cattle Further it is argued that even if human tuberculosis cannot be *communicated* to cattle or can only with difficulty be communicated to cattle it does not follow that bovine tuberculosis cannot be communicated or can only with *difficulty* be *communicated* to man Again as Lord Lister pointed out in proposing a vote of thanks to Professor Koch for his address the fact that primary *tuberculosis* of the intestinal tract is very rare in man does not, as Professor Koch maintains prove that the ingestion of tuberculous milk *is incapable of producing* tuberculous disease in the human subject for in this country at all events it has for years been a matter of common belief that tuberculous milk *produces its injurious effects* not directly upon the gastro-intestinal tract (by leading to the production of primary tuberculosis (tuberculous ulceration &c. of the intestine) but by producing tuberculous disease of the mesenteric glands [13] But coming as it *did* from the discoverer of the tubercle bacillus—the leading authority on *tubercle—Professor* Koch's opinion has *necessarily unsettled* the whole question. The matter is still *sub judice* and is being actively investigated by commissions and skilled observers all over the civilised world. In the meantime I see no reason to modify the views which I have expressed in my lecture. With some verbal alterations it is printed in the form in which it originally was written. I am most emphatically *of opinion* that until the question is definitely settled we should continue to take every precaution to prevent the *introduction of* tuberculous milk into the gastro-intestinal tract of man. Who amongst us I ask would drink milk or would allow his children to drink milk knowing that it was tuberculous?

But while I see no reason to modify the opinions which have been expressed in this lecture I devoutly hope and trust that Professor Koch's observations and views may be substantiated *for if it* should be conclusively proved after prolonged and exhaustive observation and investigation that Professor Koch is correct in thinking that bovine *tuberculosis is* incommunicable or only very slightly communicable to man, that there is, practically speaking little or no risk from the ingestion of tuberculous milk and tuberculous meat and that it is unnecessary to take any precautionary measures against bovine tuberculosis it will be a singularly *fortunate* thing for the human race. If Professor Koch's views are correct the *prevention* of *phthisis and* other forms of tuberculous disease in the human subject will *be a comparatively* simple and easy matter for then the fundamental point to be aimed at will be the destruction and disinfection of phthisical (tuberculous) sputum.

ON SOME NEW PROCEDURES FOR THE EXAMINATION OF THE BLOOD AND OF BACTERIAL CULTURES,

IN PARTICULAR

(1) ON THE POSSIBILITY OF DISPENSING WITH THE STANDARD PIPETTES AND MICROMETRICAL RULINGS OF THE HÆMOCYTOMETER,

(2) *ON A METHOD OF DETERMINING* UNDER THE MICROSCOPE THE NUMBER OF MICRO-ORGANISMS CONTAINED IN A BACTERIAL CULTURE, AND

(3) *ON A SIMPLE PROCEDURE FOR OBTAINING COAGULATION* TUBES OF STANDARD CALIBRE, *ALSO AS INTRODUCTORY TO THIS LAST A NOTE ON THE PRACTICAL IMPORT*ANCE OF THE INFORMATION OBTAINED FROM THE COAGULOMETER.

BY A. E WRIGHT, M D DUB
PROFESSOR OF PATHOLOGY ARMY MEDICAL SCHOOL, NETLEY

THE series of methods which I have described (for the most part in THE LANCET) for *measuring (a) the coagulability* [1] (*b*) the alkalinity [2] (*c*) the agglutinating power [3] (*d*) the content in calcium salts, [4] and (*e*) the bactericidal power of the blood [5], further (*f*) the method devised by my colleague Major W B Leishman R.A.M.C., for measuring the phagocytic power of the blood [6] and lastly (*g*) the method described by me for determining by a cultural process the number of living *micro-organisms* contained in a bacterial culture, [7] all involve the use of capillary tubes for the purpose of measurement. 1. In the case of the majority of the quantitative procedures enumerated above the preliminary measuring diluting and mixing operations which are involved can be carried out in uncalibrated capillary tubes by the method which I have *described* for making measurements dilutions and mixtures in such tubes. Uncalibrated capillary tubes can be used in particular *for* measuring the alkalinity the content in lime salts and the agglutinating bactericidal, and phagocytic power of the blood. It will presently appear that such tubes may be employed also in connexion with the measurements which are ancillary to the enumeration of bacteria or red blood corpuscles under the microscope. 2. For the determination by cultural processes of the number of *micro-organisms in a bacterial culture* we require capillary tubes marked off in divisions corresponding to definitely known volumes of fluid. 3. Lastly for the measurement of the coagulability of the blood—since here the area of glass surface which comes in contact with the blood comes into consideration—we require capillary tubes of a standard calibre.

I may before *dealing* with the special subject-matters of this paper briefly set out though this will involve my *traversing again* some *ground* already gone over in previous papers the system of technique which enables us (*a*) to make accurate quantitative determinations in uncalibrated capillary tubes, (*b*) to divide capillary tubes into divisions corresponding to known volumes of fluid and (*c*) to mark off upon any capillary tube a measured length which *conforms* to a standard bore.

I *Method of making quantitative estimations in uncalibrated capillary tubes.*—We proceed as follows We take in hand a piece of glass tubing heat it, and draw it out into a capillary *stem of any convenient size We provide our*selves with a rubber teat which will fit tightly upon the upper wide end of our tube and with a glass writing pencil. A mark having been placed with the last upon the capillary *stem at any convenient* distance *from its orifice* and a negative pressure having been established in the interior of the tube by means of the teat we draw up in succession into the capillary stem (*a*) a volume of the dilutand such as will suffice *to fill the* capillary stem as far as the division mark (*b*) an air bubble to serve as an *index* and (*c*) the *required* number of volumes of diluting fluid these being separated

* Under the heading of "undegenerated" were classed all those micro-organisms which took the stain in a satisfactory manner

described under 1 in the introductory part of this paper) an aliquot volume of bacterial culture with an equal volume of blood, making a film preparation of this mixture, and counting under the microscope the number of bacteria and red corpuscles found on a series of microscopic fields. The examples embodied in Table I. will show that the method is capable of giving very satisfactory results

Before describing the details of the procedure by which the above results were obtained it will be well to bring out the following points.

1. The microscopic method which is here in *question* enables us to arrive at the number of individual elements in a bacterial culture. Cultural methods give us often only the number of separate bacterial groups or bacterial hyphæ The *microscopic method* is thus applicable to the enumeration of cultures of anthrax and of those varieties of staphylococcus which, since they cannot be effectively isolated cannot be effectively enumerated by the cultural method

2. The microscopic method enables us to determine the total number of bacteria contained in a culture The cultural method *manifestly tells up at best the number of* living bacteria or bacterial groups and hyphæ contained in the culture I have *shown* in a *previous communication* that the dead bacteria in a culture of typhoid or cholera cannot be *left* out of account when we employ the culture as a [illegible]ure of the bactericidal power of the blood Much less need they be left out of account in the standardisation of a bacterial vaccine.

3. The microscopic method gives us immediately and if we so desire it anteriorly to the employment of the culture the *number of* contained bacteria. Given that we have elicited this information and that we desire to modify our culture in the direction of diminishing its content in bacteria, we can as is shown in the case of the observations designated respectively by the serial numbers 2 and 3 in Table I. dilute our cultures to the degree necessary to obtain a standard number of bacteria in the cubic millimetre. Such a preliminary standardisation of the bacterial culture employed may usefully be resorted to in the case of every estimation of the phagocytic power of the blood. As a matter of fact it was for this object that the dilutions in the tabulated observations just referred to were undertaken. A standard of 5,000 000 staphylococci per cubic millimetre was here aimed at and approximated to

A study of Table II will throw interesting light on some of the questions touched upon and also upon the question of the relative margin of error of the two different methods of bacterial enumeration.

Details of the procedure employed for the enumeration under the microscope of the number of micro-organisms in a bacterial culture —The mixture of the blood and culture in definite proportions is achieved by employing the procedure described under 1 in the introductory portion of this paper Into the uncalibrated capillary tube are filled in in each case five volumes of fluid. Of these one is in all cases a volume of blood. The other four volumes are made up, according to the estimate which we form of the probable number of bacteria in the culture or bacterial suspension which we are dealing with of either one volume of culture and three of diluting fluid or of two volumes of culture and two of diluting fluid, or of three volumes of culture and one of diluting fluid, or of four volumes of culture [11] After thorough mixture has been effected in the neck of the tube a drop of the contents is blown out upon a slide.[12] This drop is spread out by bringing down upon it the edge of another slide and drawing this along The thickness of the film is regulated by adjusting the angle between the slides, widening this angle when a thicker film is to be left behind, and narrowing it when a thinner film is required. The film is then fixed and stained most conveniently perhaps, by the stain described by my colleague, Major W B Leishman, R.A.M.C The bacteria and red blood corpuscles are now separately enumerated on a series of fields chosen at random from different parts of the preparation. Owing to the spacing out which is secured by the 5-fold dilution of the blood this enumeration can, if necessary be carried out without restricting or subdividing the field of the microscope. It, however facilitates matters if we restrict the field by the employment of a high power eye-piece and subdivide it by inscribing a cross by means of a glass writing pencil upon a cover-glass and dropping this into the eye piece. The necessary calculations can be most easily carried out by the help of a slide rule.

Finally before taking leave of the method we may note that in the case of a mixture of an agglutinating blood with a culture of the typhoid bacillus we have to deal with the conditions which were in contemplation when it was pointed out above that the method of enumeration which we are here dealing with could not be relied upon to give satisfactory results where forces were allowed to come into operation which tended to draw together the similar elements of the mixture into separate groups.

III.

ON A SIMPLE PROCEDURE FOR MAKING FOR ONESELF COAGULATION TUBES OF STANDARD CALIBRE, AND IN CONNEXION WITH THIS A NOTE ON THE PRACTICAL IMPORTANCE OF THE INFORMATION OBTAINED FROM THE COAGULOMETER.

I have in a series of papers[13] urged the importance of measuring the coagulability of the blood in connexion with clinical work I have pointed out (1) that excessive hæmorrhage supervening upon a solution of continuity of the vascular wall produced by traumatism or pathological processes is indicative of a defect in coagulability, (2) that excessive transudation of lymph (I have ventured to denote this by the term serous hæmorrhage ") is also intimately associated with a defect of blood-coagulability (3) that a deposition of fibrin upon the wall of an aneurysm can be expected only when a patient s blood possesses a high degree of coagulability and (4) that intravascular thrombosis is indicative of an unduly high blood-coagulability The evidence upon which the last of these generalisations is based is derived from experiments on animals The third generalisation is established by considerations of the *a priori* order

The evidence for the first two generalisations may appropriately be epitomised here.

It consists in part of the data of coagulo-metrical observations made upon bleeder patients. My observations conducted upon a large number of bleeders of nine different bleeder-stocks have uniformly shown that the blood of these patients is characterised by a notable defect of coagulability Proportionate to this defect is the severity of the symptoms in particular the duration of the traumatic hæmorrhages and the frequency and persistence of the subcutaneous serous hæmatomata and of the joint effusions.

A further basis for the generalisations which are here in question is supplied by observations conducted upon a variety of patients having in common only the fact that they were suffering from localised or general serous hæmorrhage. The coagulometrical observations which I have been able to make —in particular in connexion with urticaria, chilblains and general anasarca—would seem to suggest that these pathological phenomena stand in close association with a defect of blood-coagulability

I have urged that the recognition of the pathological generalisations set forth above is of fundamental importance in connexion with therapeutics For as soon as we have ascertained that a particular set of clinical symptoms is associated with a diminished or as the case may be, an increased blood-coagulability we may appropriately apply any therapeutic agent which shall have been found to increase or as the case may be, to diminish the coagulability of the blood

I may perhaps claim to have made a contribution to the building up of a scientific system of therapeutics of the disorders of the blood (*a*) by devising a coagulometer, (*b*) by establishing by coagulometrical observations that the blood may often be rendered more coagulable by the ingestion of calcium salts and in particular of calcium chloride, (*c*) by showing that there is a certain determinable optimum addition of calcium salts which cannot with advantage be exceeded (*d*) by showing that an increase of coagulability may be expected from the ingestion of calcium salts in particular where we have to deal with a defect of coagulability dependent upon a diminution of the content of the blood in lime salts, (*e*) by suggesting a method of estimating the lime salts of the blood by which the existence of this defect may be determined, (*f*) by demonstrating that internal hæmorrhage and hæmorrhage from operation wounds may be checked or kept under control by the exhibition of calcium chloride, (*g*) by demonstrating that calcium chloride will often control or abolish chilblains and urticaria (in particular the form of urticaria which supervenes upon the administration of diphtheria antitoxin and upon the consumption of acid fruits and vegetables), (*h*) by showing that the ingestion of blood decalcifying agents, such as citric acid and the administration of soap, is followed by a diminution of blood coagulability and correspondingly increased lymph effusion, and (*i*) by bringing out more clearly the fact already demonstrated by Vierordt that the ingestion of alcohol is followed by a diminution of blood coagulability

---

[11] Examples of the employment of the first and last of the mixtures here in question will be found tabulated in Table I

[12] The slide may with advantage have been cleaned and warmed immediately before use by pouring alcohol upon it and burning this off.

[13] On the Effect of the Administration of Calcium Salts in Hæmophilia and Arterial and Thickened Hæmorrhage Brit. Med Jour., July 29th 1893. Remarks on Methods of Increasing and Diminishing the Coagulability of the Blood with special reference to their Thera- [illegible] ibid July 14th, 1894. On the Treatment of the [illegible] which are associated with Deficient [illegible] Jan 8th, 1896, p 153. Note on [illegible] with Calcium Chloride British Journal [illegible] On the Association of Serous Hæmor- [illegible] tive Blood-coagulability THE LANCET [illegible] athology and Treatment of Chilblains [illegible] . 303 Discussion on the Blood in [illegible] ological Society of London 1900.

Of the therapeutical suggestions made in connexion with this work the only one which has so far been generally adopted in practice is, I apprehend, the suggestion that calcium chloride may upon occasion render useful services in connexion with the arrest of internal hæmorrhage and hæmorrhage from operation wounds. The general principle which underlies the suggestions, and which is of infinitely greater moment than any of these, has been quite overlooked This being so I may perhaps be allowed to urge that there are many indications dispersed through current medical literature which point to the need for a general advance towards that wider view of the pathology and that more rational treatment of disorders of the blood which I venture to claim is embodied in the work epitomised above I may perhaps in illustration refer to the following points.

1. The literature dealing with the treatment of aneurysm by means of gelatin injections—so much of it at any rate as is known to me—contains no reference to the practicability and expediency of determining by measurements of the coagulability of the blood before and after such injections whether the object in view, which is presumably the increase of the coagulability of the blood, is or is not advanced by this method of treatment. More than this, when recently upon the occurrence of three accidental deaths in patients under treatment by this method the suggestion was thrown out that death may have resulted from intravascular thrombosis it apparently did not suggest itself that accidents due to this cause must *a priori* be expected in connexion with any treatment which increases the coagulability of the blood. Nor apparently did it suggest itself that it would be possible to take precautions against such accidents by measuring the coagulability of the patient's blood and by taking steps to diminish that coagulability as soon as evidence was obtained of impending danger

2. In the incidental references which have from time to time been made in the medical press to the prophylactic administration of calcium chloride to patients on the eve of operation, and in the reports of a recent discussion in the course of which the efficacy of this treatment in the case of jaundiced persons was debated, it appears to have been overlooked that it would be both practicable and appropriate before proceeding to operate in a case where hæmorrhage was feared to determine whether the patient's blood has acquired the particular degree of coagulability which is desired.

3 Severe intestinal hæmorrhage supervening in the course of typhoid fever is still referred to in medical literature as if it were an unforeseeable and altogether legitimate sequela of the ulcerative processes in progress in the intestine In point of fact—and the same applies in connexion with many cases of hæmoptysis—the hæmorrhage is inordinate in quantity and is associated with a serious defect of blood-coagulability Moreover, it is possible to seek warning with a view to providing against the danger The mere fact of blood flowing profusely from a prick in the finger would of itself convey the necessary warning

4 Again, the thrombosis which is so frequent a complication of convalescence from typhoid fever and from the puerperal condition figures in medical literature as an undesirable but unavoidable complication, the supervention of which must be expected in the proper proportion of cases. A wider outlook would, on the contrary, suggest that intravascular coagulation can hardly occur, and can certainly not progress, in association with a low blood coagulability And it would further suggest that steps might be taken in typhoid fever after the period of danger from hæmorrhage had passed off to reduce the coagulability of the patient's blood. In connexion with this I may incidentally refer to the fact that Lieutenant E Blake Knox, R.A.M.C, the medical officer in charge of the acute typhoid fever wards in the Royal Victoria Hospital, Netley has recently given effect to this suggestion by putting every convalescent typhoid fever patient on a regimen of two lemons a day He informs me that, in striking contrast to what was previously the case, only one case of thrombosis, and this a case of the mildest description, has developed among some 90 successive typhoid fever patients treated by the blood decalcifying agent.[14]

5 Lastly, I may refer to the fact that urticarias supervening upon the administration of soap enemas, and urticarias supervening upon the ingestion of acid fruits and vegetables (rhubarb) are still chronicled in the medical press as events which refuse to fall into line with any known facts I have not only, as already mentioned, shown that decalcifying agents as a class when introduced into the system induce a diminution of blood coagulability, but I have, on the one hand, in myself achieved a diminution of blood coagulability and an urticaria by the ingestion of citric acid, and, on the other hand, in the dog achieved a decalcification of the blood and a diminution of blood coagulability by the administration of soap

In view of the possibility of an advance in pathology a therapeutics being made along the lines opened up by coagulometrical observations which have here been in qu tion it will be recognised that everything that conduces to t simplification and cheapening of the coagulometer, and short to its popularisation, becomes a matter of momen The way to the cheapening of the coagulometer lies narrowing down the apparatus to the bare coagulation tube and in substituting for the thick-walled coagulometer tube calibrated by the professional glass blower and scientific instrument maker, thin walled capillary tubes made by heating and drawing out ordinary glass tubing and calibrated in accordance with the principle laid down in section 3 of the introductory part of this paper

Details with regard to the method of calibration.—A preliminary word or two is required on the question of the standard calibre. A standard calibre of 0 25 millimetre was originally chosen by me for the coagulation tube It turns out, however, from a series of measurements made by filling in with mercury a variety of coagulation tubes obtained from various sources, that the suggested calibre has at best been so far conformed to as to make 0 25 millimetre the minimum calibre of the tube I have, therefore, in connexion with an abandonment of the ordinary calibration by means of standard wires in favour of a calibration with a measured volume of mercury, had to reconsider the question of the standard. I find that a convenient approximation to the wire standard of 0 25 millimetre diameter is obtained by taking as the standard for the mercury calibration a tube of a calibre such that five cubic millimetres of mercury will occupy in it a length of five centimetres

We undertake the calibration as follows Having taken a piece of ordinary glass tubing, having drawn it out into a fine and insensibly tapering capillary stem, and having sealed off this last in the flame, we introduce into the wide end of the tube five cubic millimetres of mercury measured off[15] by means of a standard five cubic millimetre pipette such as is supplied with the Gowers hæmocytometer We now as a preliminary to driving down our globule of mercury into the capillary stem break off the end of this last between finger and thumb Or better, since this avoids all chance of our mercury escaping from us through the far end of our tube, we draw out our capillary stem in the flame of peep light into an absolutely hair fine tube and then break this across. We now drive down our mercury into the capillary stem and find out by tilting the tube in such a manner as to move the mercury along whether there is any portion of the tube where the mercury column occupies a length of five centimetres. We determine this by bringing our tube down upon a piece of white paper upon which we have marked off a length of five centimetres. If we cannot find upon our tube a length which conforms to conditions of our standard we discard the tube. If on the contrary we find a length of tube which answers our requirements we mark off the upper and lower limits of this with a glass writing pencil We now for a purpose which will presently appear displace our column of mercury in the direction of the orifice of the capillary stem for a distance of from one to two centimetres We again mark off the points indicated by the upper and lower limit of the mercury and, finally, we break off our tube at the point last mentioned Before actually doing this we free the orifice of our pipette by breaking off its fine-drawn extremity, and transfer the mercury to the next tube awaiting a calibration. After calibrating a series of from six to eight tubes, we number these, inscribing the serial numbers with a glass writing pencil upon the wide upper extremities of the tubes.

---

[14] A blood-decalcifying treatment is here eminently in place, inasmuch as the ordinary typhoid fever patient will have been fed for a period of weeks upon a foodstuff (cow's milk) which contains a larger percentage of lime salts than any other I have already pointed out in THE LANCET of July 22nd 1893 that the milk might with advantage, with a view to the prevention of firm clotting in the stomach and with a view to the prevention of constipation be partially decalcified by an addition of 0·5 per cent. of citrate of soda

[15] It will be found convenient to employ a (tightly fitting) rubber teat for the purpose of drawing up the mercury into the standard pipette and for driving out this measured volume into the wide end of the tube which we propose to calibrate

Method of employing the tubes —We draw blood from the finger near the nail either by means of a prick with a hypodermic needle or by a series of pricks made with a sharp spicule of glass obtained by drawing out a piece of capillary tube. It is to be observed that the prick or pricks that we make must be generous enough to give us all the blood we require with an absolute minimum of adventitious aid If such aid is required we obtain it by winding a handerchief round the finger and making gentle pressure upon the finger pulp. The pressure must be gentle so as to avoid obtaining a mixture of lymph and blood which would coagulate more rapidly than the unmixed blood from the capillaries. As soon as a drop of blood has issued from the wound a coagulation tube which has been broken off as indicated above at the lowest pencil mark is applied to the blood This last is allowed to flow in by capillary attraction until it reaches the penultimate mark—i.e. the mark which indicates that five cubic millimetres of blood have been filled in. The orifice of the tube is now withdrawn from the blood and the tube is tilted in such a manner as to bring the column of blood into position between the two marks which delimit the portion of the tube which conforms to the standard calibre. The time of filling in each tube is noted down, both minutes and seconds The blood is now kept at the temperature of the air, if this temperature conforms approximately to the standard temperature of half blood heat (18·5° C 65–66° F) In the case where the temperature of the air is sensibly warmer or cooler than the standard temperature the tube is placed upright[16] in a vessel of water of the appropriate temperature. After the usual interval (about three minutes in the case where the blood flow from the finger prick is normal about five minutes where that flow is somewhat more free) the testing of the first tube is undertaken by blowing down the expanded upper end, the orifice being meanwhile held over a piece of white filter paper in order to detect the first shreds of fibrin. The coagulation time—i.e. the minimum time occupied by the blood in forming a definite *coagulum*—will normally approximate to five minutes

Netley

CASES OF GASTROTOMY FOR RECENT GASTRIC ULCER.

BY C W MANSELL MOULLIN M D OXON
F R C S. ENG.
SURGEON TO AND LECTURER ON SURGERY AT THE LONDON HOSPITAL.

IN two of these cases the immediate cause for operation was recurrent hæmatemesis

CASE 1.—The patient, a woman, 26 years of age who was admitted into the London Hospital on May 14th 1900 had suffered severely from attacks of indigestion for the previous 18 months. Of late the pain had been intense, coming on immediately after meals or within half an hour and radiating through from the epigastrium to the back. Until the week before admission actual vomiting had only been of occasional occurrence. Since then it had been almost constant. There had been a slight attack of hæmatemesis four months previously and other attacks becoming more severe, seven days, five days (twice) and four days (twice) previously and on the morning of admission. On the last occasion the quantity was said to have amounted to more than a pint. Shortly after admission she vomited six ounces of almost pure blood. There was no history of melæna, but an enema given the day before she came to the hospital brought away a considerable quantity of blackened blood The pulse was 140 to the minute, very small in volume and of low tension and the patient was decidedly blanched. My colleague Dr F J Smith, under whose care the patient had been admitted thinking that it was not advisable that she should be allowed the chance of losing any more blood very kindly had the case transferred to my wards and an operation was performed as soon as it could be arranged. The abdomen was opened in the middle line and the serous coat of the stomach was carefully examined. As there was no scarring or other sign of inflammation the stomach itself was packed round with sponges and was opened by a vertical incision midway between the pylorus and the cardiac end. The angles of the incision were held open by pressure-forceps and the mucous surface was systematically everted and examined bit by bit that covering the posterior wall being brought into view by introducing the hand through an opening in the great omentum and lifting the wall of the stomach into the wound A large vaginal speculum introduced through the opening in the anterior wall enabled the cardiac orifice and that part of the mucous surface which could not be brought up to be inspected without difficulty A small ulcer was found on the anterior surface near the greater curvature. It corresponded fairly well with the ordinary description of a simple ulcer and had evidently been bleeding recently There was no induration about its edges and no vessel was visible on its floor An incision was carried round the ulcer and the whole of it was excised down to the muscular coat, the gap that was left being closed by fine silk sutures which served at the same time to stop the bleeding The wound in the stomach was closed by a double set of sutures, and the opening in the abdominal wall was secured with silkworm gut. Convalescence was uninterrupted except for a slight attack of parotitis on the second and fourth days. The patient vomited once after the anæsthetic. Small quantities of hot water were given by the mouth the same evening and continued at frequent intervals for the relief of thirst, but for the first four days the feeding was carried out entirely by means of nutrient enemata. Solid food (fish) was given 10 days after the operation and a few days later the patient was placed on ordinary diet. She soon regained her strength and since the operation she has been perfectly free from the pain and indigestion which troubled her so much before.

CASE 2.—A married woman 23 years of age, was admitted into hospital on April 25th, 1900 for hæmatemesis. She was sent up in an ambulance with a history of having vomited blood at frequent intervals for four days. Shortly after admission she was sick, bringing up 15 ounces of dark coloured blood and she became very much collapsed. An operation similar to that already described was performed as soon as could be arranged. When the stomach was exposed an old cicatrix was seen near the cardiac end This was excised and then a recent but chronic ulcer with indurated edges was found by its side. In the floor of this ulcer was a bleeding branch of the gastro-epiploic artery The ulcer was included in the incision and the opening in the stomach wall, which was nearly three inches long and ran almost up to the cardiac orifice was secured by a double set of sutures The patient was very much collapsed but she rallied under injections of strychnia and caffein and rectal enemata. For the first three days vomiting was very troublesome. Then it ceased and she appeared to rally She was able to take small quantities of jelly by the mouth. The bowels acted at first after enemata and then spontaneously The tongue became moist. The abdomen was soft, not distended, and moved well with respiration. But, as in the former case, parotitis set in, first upon one side and then upon the other Suppuration followed and though relief was obtained when the abscess was opened the patient died on the ninth day after operation.

At the post mortem examination the opening in the stomach was found to be merely held together by the sutures The edges were sloughing and there was an entire absence of repair The kidneys were markedly granular and contracted It is worthy of remark that parotitis occurred in both these cases though there was suppuration in only one As there had not been any case of post-operative parotitis in my wards for at least five years before and there has been none since it almost seems as if there must have been some connexion between them, but the patients were not on the same floor or in the same ward and the one died 10 days before the other was operated upon, so that in all probability it was merely a coincidence, but it was a curious one.

---

[16] It will be found that it is unnecessary to seal up the orifice of the tube, the intervening column of air which is provided by the projecting portion of the tube suffices to keep the blood and water apart.

CASE 3—In this case, that of a patient who was under the care of Dr H J Capon, the immediate cause was uncontrollable pain and vomiting The patient was a married woman, 32 years of age For some months she had suffered in a very severe degree from all the symptoms of gastric ulcer with the exception of hæmatemesis and melæna. These had never occurred All the ordinary remedies, including prolonged rectal feeding, had been exhausted without obtaining the least permanent benefit. The patient had lost more than a third of her weight and was so weak that she could scarcely raise herself from her bed The pain came on within a few minutes after swallowing food and was especially severe at the ensiform cartilage The skin over this region was exceedingly sensitive. Vomiting shortly after food was the rule This relieved the worst of the pain but it usually continued with more or less severity for some hours after anything had been taken After consultation with Dr T J Maclagan it was decided to explore the stomach and on opening it a long, narrow ulcer with slightly thickened edges was found lying at the bottom of one of the rugæ on the anterior surface close by the incision It was about three quarters of an inch in length and extended down to, but not into the muscular coat. No other lesion of any kind could be found though the whole of the interior was carefully explored in the way already described The ulcer was excised, the mucous and submucous layers were sutured together and the stomach and abdomen were closed in the usual way In this case, also, vomiting continued for some considerable time The pain disappeared completely and finally, but owing to the sickness it was some time before the patient could take sufficient food to enable her to regain her strength. Recovery finally was complete

I may mention that in addition to these cases I published in THE LANCET in 1900[1] a series of three others in which I had operated for hæmatemesis, all of which terminated successfully, the patients recovering completely without any drawback. Of five cases, therefore, in which I have operated directly for hæmatemesis four patients have been cured, and I have little doubt myself that the fifth patient would also have survived had not her condition been so desperate

It is usually held that the advisability of operating in these cases can be settled at once by comparing the actual mortality of hæmatemesis in cases of gastric ulcer with that which it is supposed might follow gastrotomy performed under these conditions The former is put down at from 3 to 5 per cent, the latter is estimated very variously, according to the kind and severity of the cases selected. No such comparison, however, is possible under the present conditions On the one hand, the whole number of cases of hæmatemesis, trivial and severe alike (and the trivial ones are much the more numerous), is taken and the mortality percentage is calculated from that. On the other hand only those cases which are absolutely desperate, in which the operation is performed as a last chance after everything else has been tried and has failed, are reckoned at all. No one suggests, or has ever suggested, operating upon slight cases of hæmatemesis They should be placed entirely on one side and not be taken into calculation. The only comparison that can be made with any pretence at fairness is between those cases in which surgical measures are advised and declined and those in which they are advised and accepted. I have no doubt as to the result. In three of my five cases the patients were already so bloodless that transfusion had to be performed In two others I had to decline to operate altogether, they were beyond even transfusion The mortality of such cases, left to themselves without operation is certainly not 3 per cent., or even 5 per cent., it is much nearer 100 per cent. And they are the cases with which the only comparison can be made when the result of operation is the subject in question.

As no paper of this kind appears to be complete without statistics and as the statistics of the mortality from gastric ulcer and especially from hæmatemesis, vary a good deal according to the authority from whom they are taken, I asked medical registrar at the London Hospital, Dr R. C B Wall, kindly to tabulate for me all the cases of hæmatemesis from gastric ulcer which had been admitted into the London Hospital in the five years from 1895 to 1899 inclusive All cases of hæmatemesis from cirrhosis, malignant disease, &c., were carefully excluded The result is of decided interest. The total number was 246, 202 women and 44 men, and taking one year with another the numbers were very much the same in each The total number of deaths from hæmatemesis was 10, or 4 per cent But the incidence of the deaths according to age was very singular Under the age of 30 years there were 153 women with only one death Over that age there were 49 women with three deaths, or 6 cent. Taking the men there were only five under 30 yea of age with one death, and 39 over 30 years with fi deaths In other words, the mortality from hæmatemesi among the men over 30 years of age is 12½ per cent., an taking all the men together regardless of age nearly 14 pe cent. So far, then, as the question of operation for hæmatemesis is concerned there must, it appears to me, be one rule for women under 30 years of age and another for women over 30 years, and especially for men. But in considering the advisability of operating in general cases of gastric ulcer there is another point that must not be forgotten. These figures are only concerned with the mortality caused by hæmatemesis There are other causes of death in gastric ulcer besides this, and these causes must also be taken into consideration When the percentage of deaths due to these is added to that due to hæmatemesis it must be acknowledged that the death rate due to gastric ulcer, especially in the case of men or of women over 30 years of age, is much higher than is usually believed

I am fully aware that the treatment of gastric ulcer is, and must remain, in the hands of physicians But it is becoming more and more evident every day that there are certain contingencies or accidents which may occur in the course of a case of gastric ulcer which, if the consequences are to be avoided can only be met by the adoption of prompt and decisive surgical measures This is admitted so far as perforation is concerned, but I maintain that the principle should be carried much farther It should include all those cases in which, in spite of rectal feeding and other remedies, the pain after food is taken continues with severity, as it did in Case 3, in which vomiting after food obstinately persists, in which the patient is steadily losing ground, and in which medical treatment has been tried thoroughly for a sufficient length of time say for some months, and has failed

So far as hæmatemesis is concerned it is clear that age and sex make a very material difference A much greater risk may be run in the case of a woman under 30 years of age than in the case of those over 30 years, and especially in the case of men My own figures stand at only one death in 153 cases of hæmatemesis due to supposed gastric ulcer occurring in women under 30 years of age (I may say that I have reason to believe that that particular period of five years was an exceptionally lucky one.) Surgical treatment can rarely be required in them But if there is one single severe hæmorrhage in a case in which the previous history suggests the presence of a chronic gastric ulcer (when the bleeding is probably due to an opening in an artery of some size and is not merely capillary), if in any case there are two separate attacks of severe hæmatemesis at a short interval, or if there are frequent small hæmorrhages, so that the patient is becoming seriously anæmic, I believe that the risk of operation is very decidedly less than is the risk of leaving the patient alone, and that the best interests of the patient would be consulted by giving him or her the chance of operation before the condition becomes desperate

Wimpole-street W

A FEW OBSERVATIONS ON THE BLOOD PRESSURE IN MENTAL DISEASE,

WITH A NOTE ON THE TREATMENT OF MELANCHOLIA

BY H. DE M ALEXANDER, M D EDIN,
SENIOR ASSISTANT PHYSICIAN TO THE ROYAL ASYLUM, ABERDEE

THE sphygmometer of Hill and Barnard was used in t following observations and in order to ensure accuracy duplicate of the instrument was utilised The readings wer taken morning and evening at a fixed hour and the usu precautions were observed to obviate any inaccurate result which might arise from the presence of morbid physical conditions liable to produce an abnormal blood pressure. The normal blood pressure was regarded as ranging from 110 to 120 millimetres of mercury

---

[1] THE LANCET Oct 20th 1900 p 1125

Melancholia.—This affection was regarded as being divisible into four varieties—simple melancholia, acute passive melancholia, acute demonstrative melancholia, and chronic melancholia. There was no marked elevation of the blood pressure in the *simple* form of this malady whereas in the *acute passive* type the blood pressure was invariably high and remained so until the acute physical and mental symptoms abated a re-elevation occurred with each relapse of the disease. The average maximum pulsation was 155 millimetres of mercury

It is probable that the high blood pressure and high tension pulse of this affection are due to the retention in the system of certain waste products of tissue metabolism as evidenced by the marked diminution in the excretion of urea and the atonic condition of the alimentary tract. The subjective physical sensations of the melancholic are probably also due to the same cause.

Dr L. C Bruce[1] and myself have already drawn attention to the marked beneficial effect of fluid diet in conjunction with the bed treatment in shortening the acute stage of this affection and a shortened acute stage generally ensures a more rapid convalescence.

Since recording these results I have treated 10 more cases of this passive acute melancholia with satisfactory results No patient undergoing this treatment should leave bed or return to ordinary diet until his blood pressure has remained normal for at least a week or 10 days I venture to assert that it only requires the further experience and observations of others to prove that the *surallment* method of treating acute passive melancholia is unphysiological

Maudsley[2] has said regarding the use of drugs in insanity that the purely medical treatment of insanity which is not maltreatment might be comprised within a narrow compass " and of all types of mental disease his observation is most applicable to the treatment of the above form of melancholia. Plenty of water three or four pints of milk daily, the exhibition of an alkaline diuretic which does not disturb digestion—such as citrate of potassium—judicious attention to the bowels, and confinement to bed are all that are required in most cases. General tonics are of little value in the acute stage of the disease. Intestinal disinfectants such as salol have been advocated, but in the acute stage it is probable that they tend injuriously to retard the process of assimilation

Paraldehyde appears to be the best drug we have at present for the insomnia of this type of melancholia and next to it comes trional. A great objection to sulphonal is that it tends to increase the already existing constipation and thus indirectly to sustain the blood pressure. It is a common experience to see a melancholic, to whom sulphonal has been administered as a hypnotic, improve at once on the withdrawal of the drug and the administration of calomel and salines.

Acute demonstrative melancholia (agitated or excited melancholia) differs from the foregoing passive type physically as well as mentally Here we have no great diminution in the amount of urine excreted, an excretion of urea little below normal, a less elevated blood pressure, and, in the majority of cases, a leucocytosis. Bodily weight is also lost more rapidly It is thus, from a physical point of view more akin to mania.

The blood pressure was taken daily in 14 patients suffering from this variety of melancholia. It followed a more irregular course than that observed in passive melancholia, did not reach such a height, and its descent was not in all cases accompanied by a marked amelioration of the mental symptoms.

The loss of weight, which is usually a pronounced symptom in this affection is best combated by confinement to bed as long as motor restlessness or marked physical debility is present. The fluid diet treatment is also very beneficial though it does not require to be so rigidly adhered to as in the former variety of melancholia.

Patients suffering from demonstrative melancholia have usually been ill" for some considerable time before they come under asylum treatment their malady is well advanced and they as a rule, take much longer to recover than the passive melancholic.

The employment of opium in the treatment of melancholia is condemned by some authorities and advocated by others. In the acute passive type of the affection opium is certainly contra indicated by the morbid physical conditions present on the other hand, in demonstrative melancholia opium often gives surprising results, especially in cases where the malady has been existent for some lengthened period. It should be given for its effect on the 'mind and not as a hypnotic if insomnia is a distressing symptom it is best combated by trional given at bedtime but, speaking generally if the opium is producing a beneficial effect the employment of this hypnotic will be found unnecessary sleep gradually returning as the delusions become less omnipotent. We have had better results with nepenthe than with any other preparation of opium or morphia It should be given in gradually increasing doses and the amount gradually diminished as decided mental improvement is observed. While taking opium the patient should be put on an ordinary full diet and a small dose of calomel given every second or third day

Trional is the best hypnotic for the insomnia of demonstrative melancholia. To paraldehyde there are two main objections firstly it generally requires to be given in an increasing dosage, and secondly it tends to increase the motor agitation of this affection on the following morning and more especially so in those patients who have previously been addicted to alcohol.

In *chronic melancholia* the blood pressure was generally low, an elevation occurred when the mental symptoms became more acute.

Mania—Dr Maurice Craig[3] found that acute mania was associated with a low pressure, the average blood pressure in 33 cases which he examined being from 105 to 110 millimetres of mercury Although I have been able to note the blood pressure only in 16 cases of acute mania the reading obtained in each of them was invariably above normal though it never attained the height observed in acute melancholia. Mental improvement was coincident with its descent though not to such a marked extent as in melancholia. The blood pressure was much lower if exhaustion was present.

In the case of recurrent insanity examination of the pulse suffices to demonstrate the rise in arterial blood pressure which ensues coincidently with the return of excitement. In women recovering from an attack of insanity the onset of the menstrual period is often associated with a recurrence of the previous mental affection, and although the mental disturbance may be only temporary it is, as a rule, accompanied by an increase in the tension of the pulse whether the relapse be characterised by excitement or by depression The recurrence of excitement in cases of relapsing mania is usually heralded by certain premonitory symptoms such as insomnia, fits of restlessness, and sometimes by a feeling of general malaise. The blood pressure was observed to be raised from 10 to 20 millimetres of mercury during this prodromal period and it rose to a maximum as the acute attack developed. The bromide sleep" was induced in a strong adult woman suffering from a very acute attack of mania, by giving three and a half ounces of sodium bromide in four days There was no appreciable alteration in her blood pressure as the result of the administration of the drug and no benefit ensued the maniacal condition returning as the sleep passed off. When the attacks of mania and melancholia in *folie circulaire* were of the acute type the blood pressure followed the course observed in the acute idiopathic varieties of those affections. The readings obtained in *stupor* varied according to the variety of the affection In the anergic and secondary forms the blood pressure was generally subnormal and in no case more than 10 millimetres of mercury above normal on the other hand a much higher reading was obtained in the melancholic resistive variety

General paralysis presents many types of insanity and the results obtained with the sphygmometer varied extremely it being only in the later demented stages of the disease that the readings approached uniformity and the blood pressure was in every case low No alteration in the arterial pressure was observed in five cases of the disease examined before and after a congestive seizure.

Professor R. Stockman and Dr F J Charteris[4] have shown that the potassium salts when given in "ordinary quantities" do not usually cause any depressing effect on the heart or on the blood pressure in the arteries, and it would also appear that potassium bromide given in large doses has no depressing effect on the blood pressure in *epilepsy*, as in 34 cases of epileptic insanity examined a blood pressure of 130 millimetres of mercury was the average reading obtained. These patients were taking 90 grains of the drug per diem. In a case of epilepsy in a boy in whom the convulsive attacks were generally nocturnal and came on regularly nearly every day between 8 and 8.30 P M no alteration in his blood pressure was observed either before or after the seizure, on the other hand in an adult woman suffering from the status epilepticus the blood pressure fell from 140 to 90 millimetres of mercury during the short intervals between the seizures—probably as the result of exhaustion

[2] Pathology of the Mind.

[3] THE LANCET June 25th, 1898, p. 1742, and Brit Med Jour 1900

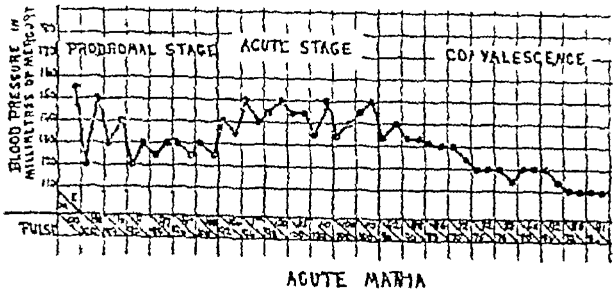
[4] Brit Med Jour 1901

In pure *senile mania and melancholia* the readings obtained corresponded to those registered in the same affections occurring in an adult or an adolescent, but the blood pressure was, as a rule, much above normal in that variety of senile insanity which is associated with dementia and which is characterised clinically by a constant fidgety motor restlessness, and it is in this form of insanity that drugs of the nitrite class are of most benefit.

In melancholia we have found the sphygmometer, in conjunction with other clinical methods, of great service in determining what stage of the affection was present and thus indicating the line of treatment to be adopted.

The blood pressure in mania appears to be considerably modified by the presence of general physical debility, and thus restlessness in the chronic maniac of poor physique is as a rule associated with a normal or even low blood pressure though an elevation may occur with any increase in excitement Without the presence of any organic disease to account for it some cases of senile dementia with constant restlessness as a marked symptom have a high blood pressure and these patients are often much benefited by the administration of such a drug as erythrol tetranitrate. As is well known an attack of mania is usually ushered in by certain premonitory symptoms and one of the commonest of these is mental depression On the appearance of any of these premonitory symptoms it is often possible to ward off the acute attack by confining the patient to bed amidst quiet surroundings and by keeping him on a low diet—precisely as a case of melancholia may be treated. I have always found the symptoms mental and physical, antecedent to an attack of mania to be accompanied by a rise in blood pressure Dr Bruce[5] stopped the onset of excitement or depression in patients labouring under *folie circulaire* by administering to them the thyroid extract and this agent lowers the blood pressure in addition to increasing metabolism The sedative and hypnotic effect induced by sulphonal in excitement has also been found to be attended by a reduction of blood pressure

I believe that mania is associated with a higher blood pressure than that attributed to it by Dr Craig and Dr W R. Dawson[6] and also that the sedative effect of a hot bath on the excitement of an acute maniac is in part due to the reduction of blood pressure induced by this method of treatment The "bed treatment" in cases of mania also tends to produce the same result by preserving the patient from sensory and emotional irritation.



I append a chart illustrating the course of the blood pressure observed in a case of acute mania which was under observation from the commencement of the affection

VERMIFORM APPENDIX, CONTAINING FÆCAL CONCRETION ON A BLACK PIN, REMOVED AFTER DEATH FROM A CHILD, AGED SIX YEARS,

ILLNESS TWO DAYS AND NO MEDICAL MAN CONSULTED

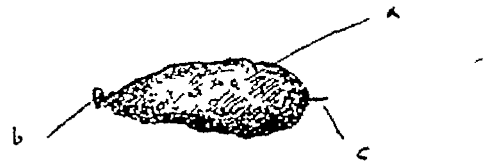
BY JOHN D MALCOLM, F R C S EDIN,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

THE concretion which is figured below was exhibited at the meeting of the Pathological Society of London on April 29th, 1902. It was sent to me, with the vermiform appendix in which it was found, by Dr Percy Rendall of Ewell, and Dr C Hubert Roberts has kindly made the accompanying sketches

The patient, a female child, whose illness lasted for two days, was not attended by any medical man, but Dr Rendall was sent for after her death. He was told that the girl was six years old and had shown no evidence of abdominal mischief before Oct. 7th, 1901. On that day she was at school and quite well. In the evening she was seized with violent pain in the abdomen, vomiting, and diarrhœa. The next day she was better, off and on, but on the 9th she died suddenly The body was opened by order of the coroner The small intestine and mesentery were found to be glued together by inflammatory adhesions so as to shut off the pelvic cavity The appendix was in a gangrenous state beneath the adherent coils and close to the peritoneum covering the sacrum Liquid fæces had exuded and had filled the pelvic cavity On incising the appendix the concretion was exposed and it was noted that the point of the pin was directed towards the tip of the appendix Before the drawing was made the concretion had shrunk so as to expose more of the head and point of the pin than was shown in the fresh moist state.

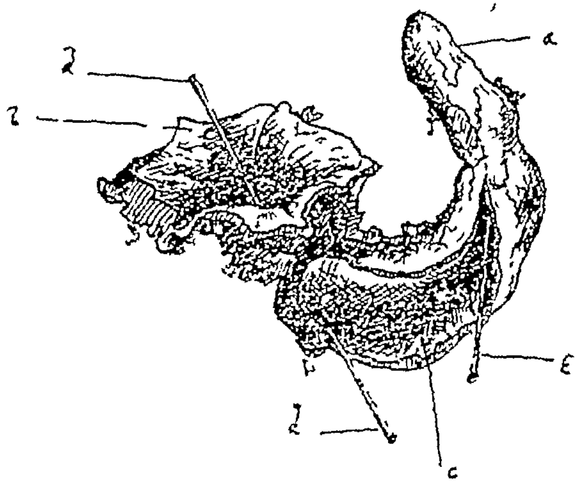
The case is interesting as it shows that the most serious mischief connected with the vermiform appendix may excite

FIG 1



Concretion —*a* The concretion *b*, Head of pin *c*, Point of pin.

FIG 2



Appendix and part of cæcum —*a* Free end of appendix vermiformis *b* Portion of cæcum removed with appendix *c* Portion of appendix opened up to show region which contained the concretion shown in Fig 1 *d d* Glass rod passed through from cæcum to opening in appendix *e* Glass rod passed into canal towards the blind end of appendix no real anxiety in the minds of a patient's friends. Prompt interference by operation was the only treatment that offered any chance of saving the patient's life, but if a medical man had been consulted immediately after the onset of symptoms it is obvious that examination of the parts in a child aged six years would have been difficult and unsatisfactory and the surgeon however great his experience might have failed to grasp the full gravity of the case in time to perform a successful operation

DIFFICULTIES IN THE DIAGNOSIS OF SMALL-POX.

BY W T FREEMAN M.D DURH F R.C.S. ENG

AN interesting paper on the above subject by Dr W M Young appears in THE LANCET of June 7th p 1598. The following case also seems worth reporting

An unhealthy looking boy 10 years old, was seen by Mr J G Braden of Reading on March 15th 1902. The patient was feverish and covered with a rash of the scarlatiniform type. There was some subsequent peeling but no albuminuria. The case was notified as one of scarlet fever He soon became better of this attack but on March 25th to the 27th he again became very ill. His temperature was high (from 100° to 103° F) and node-like swellings appeared on the front of the tibia and over the forehead and left orbit. He had also swelling apparently both in and around the left knee-joint. I saw the boy in consultation with Mr Braden on April 3rd and he had still a high temperature and the swellings referred to were still in evidence, and he had developed additionally a profuse bullous rash the vesicles or bullæ ran in size from that of a pin's head to near the diameter of a shilling piece. The bullæ were principally grouped on the legs and buttocks, but some were also present on the arms and lower abdomen. Some of them had an umbilicated appearance and all were hæmorrhagic. They were commencing to dry up but tests applied as carefully as possible practically proved them to be multilocular The history of this second rash was that it first appeared as a papular one and subsequently became vesicular and bullous. There was a largish bulla on the left side of the tongue. The boy seemed to be very ill. He had all the appearances of a congenital syphilitic—typical upper incisors, flattened bridge of nose, scars at the angle of the mouth &c He had good vaccination marks but had not been re vaccinated On the 7th he was much improved the vesicles and bullæ were dried up into hæmorrhagic scabs, the swellings had nearly disappeared and the temperature was normal The patient recovered.

When I saw him on April 3rd I could not help wondering whether we were not dealing with an anomalous case of variola in a partially protected but specifically unhealthy child The scarlatiniform rash, I thought, possibly might have been a prodromal rash and I was particularly impressed with the multilocular character of the lesions. The patient had been previously seen by the medical officer of health of Reading (Dr A. Ashby) and we all determined to hold our hands as to variola. Dr Ashby was not much in favour of small pox and I declared myself more in favour of a peculiar bullous form of peliosis rheumatica than of variola, although the apparent multilocular character of the lesions was puzzling Upon a second visit, paid two days later I gave up the last shred of an idea of its having been the more formidable infectious disorder I believe that the whole condition was a developmental erythema—an erythema of the nodose type passing on through stages to a bullous type of rheumatic purpura. An unhealthy subject amidst not the best of surroundings and with a syphilitic taint, the boy was no doubt predisposed to the anomalies, both subjective and objective.

It is right to add that Mr Braden, the patient's original medical attendant, is still inclined to think that the primary rash was scarlet fever and that the symptoms and rash of ten days later were of distinct origin. It should also be added that as the boy improved he was vaccinated and a full reaction resulted.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET

A CASE OF BILATERAL STRANGULATED HERNIA IN AN INFANT

(Under the care of Mr T. H. KELLOCK.)

IN infants under the age of one year it is rare for strangulated inguinal hernia to occur but it must be extremely rarely that in a young child strangulation should occur in herniæ on both sides of the body In THE LANCET of June 1st, 1901 p 1536 we quoted some statistics as to the occurrence of strangulated hernia in infants, to which we refer our readers.

An infant, aged 10 weeks, was admitted to the Hospital for Sick Children Great Ormond street, on March 8th, for irreducible right inguinal hernia. The mother stated that when the child was seven weeks old she first noticed a swelling in the right groin for this she attended the out-patient department and circumcision was performed on March 4th at that time the hernia disappeared when the child was quiet and still She had never noticed any swelling on the left side. On the 6th the swelling was noticed to become larger and more tense and could not be got back it remained down for the two following days, during which the child was very fretful and vomited occasionally after taking the bottle. On admission the patient appeared to be a healthy well nourished child but very fretful crying almost continuously he had a hernia in the right inguinal region which was found to be irreducible under an anæsthetic it was therefore operated on and was found to contain a knuckle of small intestine tightly constricted at the inguinal ring which was very small. The bowel was dark blue in colour and deeply marked where it had been constricted There was an almost total absence of fluid in the sac. Before the bowel could be reduced a rather free incision had to be made in the constriction at the neck of the sac and after it had been reduced the sac—to which the vas deferens was closely adherent—was ligatured at the neck and removed. Two silk sutures were used to close the inguinal canal. The external wound was sutured and dressed with gauze and collodion.

The child progressed favourably but cried a great deal. On March 10th a hernia was found in the left inguinal region which was reduced with some difficulty On the 18th the wound was healed and the stitches were removed On this day the hernia on the left side was present again but was easily reduced On the 19th the child was discharged wearing a skein truss on the left side. He was re-admitted four days later the hernia in the left groin having been irreducible for five hours. On the evening of that day an operation was performed and there was found an almost precisely identical condition to that which had been seen on the right side. The same treatment was adopted the wound healed rapidly and he was again discharged. When seen some time afterwards in the out-patient department the condition was quite satisfactory the wounds were soundly healed and there was no sign of return of either hernia.

Remarks by Mr KELLOCK.—Except for the rarity of strangulated hernia occurring on both sides at so short an interval there is little in this case calling for comment. The child had probably a partially closed funicular process of peritoneum on both sides and into these successively the almost constant pressure from crying drove a knuckle of intestine. The inguinal rings on both sides were very small and had to be rather freely incised before the bowel could be reduced This is probably always the most difficult part of the operation in an infant and it is better to be free with the incision rather than to use any force in attempting to reduce the very slender and congested bowel The absence of fluid in both sacs was perhaps rather unusual and necessitated an extra amount of care in opening them.

LEICESTER INFIRMARY

A CASE OF DECIDUOMA MALIGNUM

(Under the care of Mr H. J BLAKESLEY and Dr R. SEVESTRE.)

CASES of deciduoma malignum are of sufficient rarity to make it desirable that they should be published, especially when the post-mortem and histological records are complete. The following case illustrates well all the typical features of the disease.

A married woman, aged 31 years, was admitted into the Leicester Infirmary in October, 1901. She stated that eight months before admission she had passed through a normal confinement, being attended by a midwife, and that one month afterwards menstruation occurred naturally 10 weeks after her confinement she began to lose blood per vaginam and continued to do so up to the date of admission except for short periods when blood stained fluid was observed She had been rapidly failing in health and losing flesh, especially during the last three months, and had complained of severe cough for about three weeks, with dyspnœa of late on the slightest exertion. Four or five days previously to admission she had noticed two swellings on the left side of the vulva. The patient's history was as follows She began to menstruate at the age of 14 years and was married at 21 years. She had had seven children, three of whom were still born, she had had no miscarriages On admission her condition was that of an emaciated and anæmic woman with flushed cheeks and frequent short dry cough and raised temperature She did not complain of any pain. On examination of the heart a systolic murmur was heard which from its position and character was believed to be hæmic in origin. Coarse moist sounds were heard over the lungs which were most marked at their bases On abdominal examination nothing of an abnormal character was found On vaginal examination an oval, smooth, non fluctuating swelling of a deep purple colour and of about the size of a walnut was found situated on the inner aspect of the posterior half of the left labium majus, immediately internal to this, but separate from it, was a smaller swelling of a similar character, with superficial ulceration on its surface The cervix was in the middle line and was patulous and torn on the left side. Bimanually the uterus was felt to be enlarged and retroverted but moveable. The catheter specimen of the urine was found to be free from albumin and sugar The case was believed to be one of retained products of conception

On the third day after admission the patient was anæsthetised with ether, the cervix was drawn down by a vulsellum, and after Nos. 12, 13, and 14 Hegar's dilators had been passed the finger was introduced. A lobulated, firm, sessile mass was felt occupying the cavity of the uterus, being attached to the left upper half of the organ, by means of the finger and curette the greater part of the mass was removed piecemeal The fragments removed had the appearance of hardened placental tissue. The amount of blood lost during this procedure was very small in quantity and the uterus contracted firmly On incising the mucous membrane over the swellings in the vulva their contents readily shelled out and consisted of blood clot with firmer strands running through them The patient rallied well after the operation, there was no further hæmorrhage, only a slight blood stained watery discharge. Her general condition appeared to improve after the operation for a few days, but very soon the lung symptoms became more severe, the temperature ranged between 101° and 102° F, but there were no rigors or other evidence of septic infection, and she died on the seventeenth day after admission

Portions of the material removed by the curette were sent to the Clinical Research Association and the report received was to the effect that it was a case of deciduoma malignum

Necropsy.—At the post-mortem examination the uterus was found to be larger than normal. On its anterior surface between the middle line and the upper part of the left broad ligament were two tuberosities placed almost vertically, but quite separate from each other which were clearly portions of growth Each tuberosity had a smooth and rounded outline, the lower one, the larger of the two, was inclined to be conical in shape, with a base of about one inch in diameter In colour they were dark red To the touch they were softer than the surrounding parts but did not give the sense of fluctuation, the peritoneum covering them was smooth and bright. The rest of the external aspect of the uterus presented a normal appearance. The uterus was opened by a vertical incision on its anterior aspect. Its cavity presented the appearance that would be expected after curettage except in the part beneath the tuberosities, where the surface was irregular and of a dark red colour, this clearly being a portion of the growth that the curette had not reached. On the left labium majus there were two raw surfaces from which growths had been removed at the operation Both lungs were studded on their surfaces with secondary growths which in outline were round and of a dark red colour, these growths were more numerous at the base than at the apex, the largest being of about the size of a walnut On section of one of these secondary nodules a reticulated appearance was seen with what appeared to be blood clot in the spaces. It was not found possible to make a complete post-mortem examination but no evidence of growth was observed in other organs

On examining a microscopic section of the uterus the margin of the growth was seen to be made of masses of cells forcing their way into the surrounding tissue. These cells were not arranged in alveoli Internally to the growing margin were seen the remains of the cells of the normal tissue with cells of the new growth and much extravasated blood, this gradually merged into a part where no definite structure could be made out but which appeared to consist of blood clot and broken down tissue. On further examining the growing margin two varieties of cells were to be seen The greater number of cells which had no stroma between them were larger and round or ovoid, with deeply staining nuclei, in some the nucleus had contracted to one side, leaving a vacuole. Besides these single cells there were here and there masses of protoplasm containing a number of nuclei, the so called syncytium, on closer examination, however, these multi nucleated masses suggested that they were made up of numbers of large ovoid cells fused together There was no appearance of new fibrous tissue. Immediately behind the growing margin a section showed patches of extravasated blood mixed with the tumour cells and it was by no means easy to say what relation the blood vessels had to the cells of the tumour

Remarks by Mr BLAKESLEY *and* Dr SEVESTRE.—This case illustrates the chief symptoms of the disease, in the first place following on pregnancy, in a multipara, the early appearance and continuance of hæmorrhage, the rapid wasting with hectic temperature, and signs pointing to extensive disease of the lungs Most of the above symptoms and signs are such as are common to cases of retained products of conception and, as a rule, the diagnosis is made from microscopic section of a portion of the growth after removal. It further illustrates the extreme malignancy of this disease, death occurring seven months after the history of its commencement Although the signs and symptoms of this disease are sufficiently clear for it to have a distinct clinical entity the same cannot be said of its pathological character and there is much diversity of opinion as to whether it should be classed among the carcinomata or sarcomata. The distribution of the secondary growths by the blood stream and some of the features noticed in the description of the microscopic section appear to support the view, which is generally held, that these tumours ought to be classed among the sarcomata.

Several views are held in regard to the origin of these tumours, by some it is thought that they arise in the uterine tissues and are modified by pregnancy or its results, by others that they arise in decidual tissues It is important to remember that these tumours always occur within a few weeks or months after abortion or delivery at term or not infrequently after the condition called hydatidiform mole. If it arises in tissues not connected with the decidua of pregnancy it is curious that its effects are noticed after delivery and not before. As regards the structures in the decidua from which the tumour may arise there is much diversity of opinion and this point is not likely to be settled till more is known of the tissues in which the placenta arises. By some the growth is considered to be a carcinoma and this view is based on the resemblance of cells to the syncytium of the chorionic villi, the syncytium being considered to be epiblastic in origin Whatever may be the ultimate views held as to its origin, it is at present clear that in regard to rapidity of growth, dissemination and the short time it takes to destroy life, it must be considered as one of the most malignant tumours known.

OPHTHALMOLOGICAL SOCIETY

Secondary Carcinoma of the Eye —Leprous Ulcer of the Cornea.—A Doubtful Case of Atropine Poisoning —Bilateral Congenital Microphthalmos —Colloid Degeneration of the Conjunctiva —Exhibition of Cases and Card Specimens.

AN ordinary meeting of this society was held on June 12th Dr DAVID LITTLE, the President, being in the chair

Dr W C ROCKLIFFE (Hull) read notes of the termination of his case of Secondary Carcinoma of the Eye exhibited to the society in July 1901. The left eye was excised on July 12th, 1901, and the specimen and slide, kindly mounted by Mr W T Lister then pathologist to the Royal London Ophthalmic Hospital showed the cornea to be healthy with a rather shallow anterior chamber the angle being narrowed but not closed the lens being apparently healthy and *in situ* and the vitreous entirely absorbed. Situated at the posterior part and extending from the optic nerve to the ciliary processes was a large flat unpigmented tumour (which at the optic nerve appeared to be about from two to three millimetres in thickness and gradually tapered as it advanced) originating in the choroid The retina was completely detached. Microscopically the growth was limited to the choroid and consisted of numerous round cells grouped together with connective tissue Hardly any pigment cells were discernible except in the anterior half of the choroid where they lay internally to the new growth and from which they appeared to be entirely free. The vessels were new and were entirely confined to the connective tissue network. The optic nerve also had several tumour cells scattered among its fibres and the sclerotic at the posterior portion was sparsely infiltrated with the same. There were several areas of degeneration in this growth. On July 30th vision in the right eye was $\frac{6}{18}$ Detachment of the retina was increased and there was shooting pain round the eyeball. On August 10th there was an attack of pleurisy from which the patient appeared to recover but later there were stiffness, pain and swelling in the left leg The right optic disc was congested and the entire retina was swollen and further detached. The patient died on Nov 30th, the most troublesome symptoms having been vomiting and paroxysmal cough. Vision had gradually deteriorated but there was little or no pain in the head or in the eye. The patient had also continual constipation and was comatose during the last 48 hours. It appeared that secondary carcinoma of the eye more commonly followed carcinoma of the breast, affecting females rather than males between the ages of 40 and 60 years. The tumour was flat and consequently tension was not increased Duration of life, though varying after the first appearance of eye symptoms did not usually exceed two years.—Mr W T HOLMES SPICER cited a case in which metastasis occurred in one eye 30 months after removal of the breast for cancer Two separate detachments of the retina were noted, the appearance varied but the tension was not raised. Nutrition being good the eye was removed a few weeks ago and flat scirrhous growths were found opposite the detachments It was a difficult point to decide whether the eye should be removed in these cases.—Mr A. HILL GRIFFITH said that these flat wafer like growths were usually due to carcinoma of the choroid following a primary growth in the breast. He thought however that sarcoma of the choroid if seen in an early stage would have a similar appearance and he cited a case in which he had removed an eye having this appearance and had found the growth to be sarcoma.—Mr C DEVEREUX MARSHALL said that the tendency of carcinoma was to spread laterally whereas sarcoma assumed a mushroom shape but in the early stage the resemblance was very close Carcinoma occurred secondarily in the eye probably more often than had been supposed and since attention had been directed to the matter several cases had been recorded. In advanced cases of cancer defects in the eye were either overlooked or not paid much attention to

Dr ROCKLIFFE then read notes of a case of Leprous Ulcer of the Cornea in a young man a native of the West Indies. He exhibited prints of skiagrams showing the various bone changes taking place in this disease. He also referred to the obstinacy of the corneal ulcer to treatment in spite of frequent galvano-cauterisation &c.

Dr ROCKLIFFE also read notes of a case of Supposed Death from Atropine Poisoning The patient (one of four survivors of a family of 12) was a very delicate looking child aged 10 months who had suffered from convulsions most of this time. He first of all put three drops of a 1 per cent. solution of atropine in the eyes which did not dilate the pupils fully More atropine was applied but during the 30 hours which elapsed from the first using of the atropine only seven drops were used one-seventeenth of a grain. The temperature rose to 105·6° F The pulse was uncountable and the respirations were 72 the skin was red and the lips had a quantity of mucus about them. In this state the child died Nothing abnormal was found post mortem

Dr A. BRONNER (Bradford) read notes on Two Families with Bilateral Congenital Microphthalmos and Cataract. In one case the father and four out of eight children were affected, these were numbers 3, 5, 6 and 8. The eyes of the mother were normal. There was no consanguinity nor was there any history of syphilis In the other series the mother and all the four children were similarly affected The paternity of the children was somewhat uncertain. The maternal grandmother was said to have had similar eyes.—Dr D ARGYLL ROBERTSON had once operated on a boy with this condition the father having similar eyes and having previously undergone a successful operation for the removal of his cataract. In both fair vision resulted, though the eye was only two-thirds of the normal size —Dr P H MULES thought that in such cases there was usually congenital syphilis. He referred to two cases of the kind.—Mr PRIESTLEY SMITH said that there was no hard and fast line to be drawn between the small eye and the microphthalmic one. If the diminished size was very marked probably the lens was small and opaque, but if the lens was clear and full sized then glaucoma was almost certain to result. On the whole he thought that the subjects of the former variety were less liable to become blind than were those of the latter He had attended a father and daughter with small eyes, the cornea measuring only 10½ millimetres. Both had glaucoma.—Mr W A. FROST thought that those having a congenital coloboma were less liable to glaucoma.—Professor FUCHS (Vienna) had seen but one case a man who had lost an eye from acute blenorrhœa had a child who suffered from microphthalmos on the same side.

Major H. HERBERT I.M.S described a case of Colloid Degeneration of the Conjunctiva. This affection had been wrongly named amyloid" or hyalin" degeneration. Similar changes had been found rarely in the skin of old people and had been correctly described by dermatologists as colloid degeneration. The ocular conjunctivæ only were affected the palpebral portions being occupied by scar tissue from old trachoma a swollen translucent fold over hung the upper third of each cornea. The change consisted mainly in a swelling and breaking up and rearrangement of white connective tissue fibres (collagenous) and also of elastic fibres. In the deeper tissues the new material became moulded into rounded and elliptical blocks probably by constant stretching and movement of the fold In the centre of many of these blocks plasma cells were inclosed more rarely smaller masses of colloid or masses of blood pigment. Other blocks with central cavities represented the remains of blood vessels On the other hand other blood vessels had undergone rarefaction of their walls instead of colloid thickening and occlusion. Many of the blocks had connective tissue cells closely applied to them Special staining with acid fuchsin and acid orcein showed imbedded in many of the blocks the remains of white connective tissue fibres and in others elastic fibres. But the change was so advanced in the tissue examined that it was only close beneath the epithelium in a layer of adenoid tissue that the transition from collagen to colloid could be followed. In this layer a few true hyalin balls were to be found and both here and in the deeper tissues many golden pigment granules the remains of hæmorrhages Here and there some of the deeper colloid had coalesced into large and rather firm opaque waxy masses two or three millimetres or more in diameter In the central portions of these masses there were no blood-vessels and only the remains of cells, consisting of groups of small particles and larger spheres with some affinity for hæmatoxylin. There were still a few bands of white connective tissue remaining, but they were degenerating on lines rather apart from the primary colloid change, there were also some free elastic fibres mostly clumped near blood vessels. Some of the latter showed basophile degeneration—elacin. The only approach to amyloid reaction found was a faint indigo-blue with iodine and sulphuric acid in a few of the blocks, all alike stained pale brown with iodine alone and none of them gave any trace of pink with methyl and gentian violet.

The following cases and card specimens were shown —

Major M T YARR, R.A.M C Indirect Contusion Injuries of the Left Eye resulting in Blindness, following a Mauser bullet wound of both superior maxillary regions.

Mr J H. PARSONS Sections of a case of Microphthalmos

Dr LESLIE BUCHANAN Traumatic Separation of the Ciliary Body from the Sclera.

Mr M. STEPHEN MAYOU (1) Rodent Ulcer of the Face treated by X Rays, and (2) a case of Trachoma treated by X Rays

Mr ARNOLD LAWSON Partial Embolism of the Central Artery of the Retina in a lad, aged 18 years

Mr SPICER (1) Thrombosis of the Retinal Veins, with Cystic Degeneration of the Retina and Yellow Spot, and (2) Vessels of New Formation on the Anterior Surface of the Iris

The Bowman Lecture

The Bowman Lecture was delivered before the Ophthalmological Society on June 13th by Professor ERNST FUCHS of Vienna. It was a learned address on an avowedly intricate subject and was illustrated by enlarged drawings not yet in a state for reproduction

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN

Heart Disease in Children.—Infantile Paralysis—Displacement of Testes—Fleeting Amauroses in Children presenting Symptoms of Meningitis—Hypertrophy of the Right Great Toe

THE provincial meeting of this society was held at Manchester on June 21st, Dr HENRY ASHBY (Manchester) being in the chair Prior to the meeting, which was held at 4 P M and at which many London and provincial representatives were present, cases were demonstrated in the wards of the Manchester Hospital for Children by the honorary medical staff.

Dr A. E SANSOM read a paper on Heart Disease in Children He said that the chief affections of the organ were rheumatic, but not always, and were not often associated with painful and diseased joints The chief groups of them were (1) the temporarily swollen and enlarged heart of rheumatism, (2) the heart of rheumatic pericarditis, (3) the heart of rheumatic endocarditis with resulting valvular disease, and (4) the heart of slow and insidious rheumatic endocarditis inducing mitral stenosis.—Dr E CAUTLEY showed a specimen of Atresia of the Conus Pulmonalis and Patency of the Septum Ventriculorum The child died at 12 months of age from cardiac failure during an attack of dyspnœa. Dr Cautley thought that cases of congenital heart disease should be divided into two groups—those due to developmental error and those due to fœtal endocarditis Occasionally the two factors might be coexistent. He regarded congenital syphilis as the first cause of developmental error —Dr THEODORE FISHER (Bristol) thought that the most striking feature of heart disease in children was pericarditis. Dilatation slight in amount occurring in rheumatism was not serious He thought that myocarditis and pericarditis showed that the heart was poisoned as a whole He agreed with Dr Cautley's classification of congenital heart disease. A patent foramen ovale was very common and could be found in one fourth of adult necropsies if it were looked for

Mr W P MONTGOMERY (Manchester) read a paper on the Results of Tendon transplantation in 25 Cases of Infantile Paralysis of the Lower Extremity The cases were classified into various groups and the results of the various methods employed were given The work of re education was often very slow but the final state was good A number of cases were shown in the wards prior to the meeting

Dr C N GWYNNE (Sheffield) read the notes of a case of Infantile Paralysis of the Leg which he had treated by excision of the knee, the ankle, and the tarsal joints The result was most satisfactory and the boy could walk well, though with a stiff leg, but without any evidence of deformity beyond some shortening —Mr R CLEMENT LUCAS spoke of the old fashioned way of treating such cases by tenotomy with results which were not encouraging and of the great advance of the present methods He had himself done more in the way of excising the bone in the extreme cases of deformity than had been done in the present series. —Mr WALTER EDMUNDS thought the cases were very successful and regretted the shortness of the time at the disposal of the society for discussion —Mr JOSEPH COLLIER (Manchester) agreed that the best way was to graft tendon on to the periosteum, if that could be done and the tendon were long enough He had more experience of arthrodesis in cases where the limb was flail like

Mr CLEMENT LUCAS read a communication on a case of Displacement of both Testes in Perineo with an Inguino-Perineal Hernia on the Right Side No deformity had been noticed till the sudden descent of a hernia on the right side at the age of three years drew attention to the displacements A photograph showing the double displacement was exhibited A radical cure of the hernia and replacement of the testes had been affected.

Mr SYDNEY STEPHENSON related a series of cases in infants who while suffering from symptoms indicative of Posterior Basal Meningitis became Blind without Ophthalmoscopic Changes Sight was ultimately completely recovered The title of his paper was Fleeting Amauroses in Children presenting Symptoms of Meningitis

Dr R C DUN (Liverpool) read notes of a case of Hypertrophy of the Right Great Toe (radiograms, photographs, and a cast of the foot were shown) The deformity occurred in a girl, seven and a half years of age, and no overgrowth had been noticed until the child was five years old The whole of the tissues of the toe were increased, the bones taking part in the hypertrophy The greatest development was of a lipomatous nature A definite fatty mass was present on the dorsal surface of the terminal phalanx.—Mr CLEMENT LUCAS said that many such cases of hypertrophy were nævoid lipomata and asked if there was any nævoid condition of the toe and Dr DUN replied that there was not.

After a vote of thanks to the chairman and to the hospital authorities for the use of the hospital the meeting terminated

Subsequently dinner was served at the Queen's Hotel, Dr SANSOM presiding The dinner was well patronised and it passed off successfully

On the following day the members and their friends enjoyed a trip into Derbyshire. After a country drive from Grindelford luncheon awaited the party at the "Peacock," Baslow, where they also partook of tea after a visit to Chatsworth, and they were subsequently driven to Bakewell station in time for the evening train for London and for that for Manchester and Liverpool

The provincial meeting next year will take place at Brighton

The annual general meeting of the society will be held at the Hotel Cecil, London, at 6 30 P M on Wednesday, July 16th and will be followed by dinner at 7 30 P M, at which guests will be welcomed Dr Henry Ashby will be in the chair

---

BOARDS OF GUARDIANS AND VACCINATION —The public vaccinators of St. Germans, Cornwall, have forwarded a petition to the Local Government Board in reference to vaccination in the St Germans Union. The petitioners complain that since Jan. 1st, 1902, in compliance with demands from the clerk of the guardians, they have been compelled to send their vaccination registers on five occasions Consequently they have been unable to enter particulars in the register at the time of vaccination and inspection The petition, in conclusion, adds "that in view of the pressure brought by various boards of guardians to prevent persons availing themselves of the benefits of the Vaccination Acts it would be for the public advantage if the administration of the Acts was taken out of the hands of the local authorities, and that public vaccinators should carry out their duties directly under the Local Government Board"

Reviews and Notices of Books.

A Handbook of the Gnats or Mosquitoes giving the Anatomy and Life history of the Culicidæ together with Descriptions of all Species noticed up to the Present Date By Lieutenant-Colonel G M. GILES, M.B. Lond. F.R.C S. Eng I.M.S (retired) Second edition London John Bale Sons, and Danielsson Pp. 530, 17 Plates, and 53 Figures in the text. 1902. Price 21*s*. net, post free abroad 22*s* 6*d*

THE appearance of this second edition of Lieutenant-Colonel Giles s well known work is not precisely opportune. We have just noticed the recently published monograph of this group by Mr Theobald which seems to include most of the information gathered together in this book and which is a good deal fuller in the systematic part. Nor is the present work so extremely low in price as to render it a ' cheap substitute" for the fuller monograph issued by the Trustees of the British Museum. All this, however is not in the least Lieutenant-Colonel Giles s fault and if his publishers chose to bring out a second edition at the present juncture that is their affair But it is difficult to understand why they did not produce a work of more attractive appearance and handier in size. The author himself does not enlighten us much as to the reasons which led him to comply with the demand on the part of his publishers for a new and revised edition. He has admittedly culled from the pages of Mr Theobald s three volumes the descriptions of such species as were not described in the earlier edition In justice to Lieutenant-Colonel Giles however we may point out that the introductory chapter dealing with structure, life-history and the connexion of mosquitoes with malaria occupies a considerably larger number of pages than are devoted to these aspects of the matter in the British Museum treatise the latter indeed is mainly systematic. Moreover—and this unquestionably adds to the value of the book—the present author has depended largely upon his own first-hand knowledge in preparing his handbook. We should have thought, however that a couple of months of constant work with the microtome and by dissection " was by no means an excessive amount of labour to bestow upon so important and vast a subject. The volume bears evident traces of an enthusiasm for the subject , so marked indeed is this that Lieutenant-Colonel Giles reads mosquitoes into everything and even where he is writing of the flea terms the family to which the pest belongs culicidæ" instead of pulicidæ. All the chief facts about these pestilent flies are brought out with clearness and the reader will undoubtedly find himself after studying the author s statements a master of what is to be known generally about the group. The illustrations though not by any means perfection are at least intelligible and will aid the reader greatly

Early in the book Lieutenant-Colonel Giles dispels a common error of newspaper correspondents concerning the mosquito. Everyone has observed from time to time a paragraph relating to the arrival of mosquitoes in this country and the reason for the arrival is attributed to the hot weather The latter part of the statement is, as a rule correct, but there is no arrival. The local swamp and pool provide us with sufficient mosquitoes of home growth which are quite up to the recognised standard in biting capacity But, as the author justly observes, as a rule they do not bite unless under the provocation of extreme heat. Hence the energy of the Indian bred species and we may add from personal experience, those of Lapland which are not a whit inferior in biting power and close application to their business to any mosquito that can be hatched elsewhere. The mosquito—and, of course by this word we understand members of the family culicidæ and not any and every biting and stinging winged creature—is, curiously enough, not naturally a bloodsucker at all. In India the author observed that the contents of the alimentary canal of both sexes consisted largely of pollen grains, the occurrence of which he remarks incidentally has led to some confusion with the parasites which the mosquitoes convey An inexpert microscopist might confuse the vegetable cell with an animal parasite. Besides pollen mosquitoes enjoy the preserved fruit and sweets laid out for dessert on an Anglo-Indian dining table" and generally anything that is semi liquid and toothsome. That they feed often, and perhaps usually by piercing the tender stems of plants, has long been known and Lieutenant-Colonel Giles is so desirous of emphasising this really rather well known fact that he actually mentions it twice on the same page. We notice indeed a little tendency here and there to unnecessary repetition, to be explained perhaps by the somewhat hasty preparation of this second edition. For instance, the author refers twice to the uninstructed paragraph of the English newspaper concerning the supposed advent of immigrants of the culex family The mosquito winds its sultry horn," as might be supposed, mainly in hot weather But, oddly enough, it does not like direct sunlight it haunts shady corners. But the larva, at any rate of anopheles, must have sunlight, so different are the two phases of life of this parasite.

The author gives some important information which has a bearing upon the spread of these flies from country to country Such minute creatures might well be supposed to have no geographical distribution in particular Here, as elsewhere, it is almost impossible to distinguish between indigenous species and those which owe their occurrence in any given country to direct, though unintentional, transport by man. Thus the ubiquitous mouse has gained this epithet through the commercialism of man. The cockroach and that unmentionable six legged denizen of bedsteads were once rare oriental creatures. Lieutenant Colonel Giles especially points out that the sea sea air and sea water are fatal to both mosquitoes and their larvæ. While serving as naturalist," he writes 'to the Indian Marine Survey I was necessarily at sea for months together and though butterflies dragonflies and other flying insects often boarded us far out at sea I found no evidence of small and delicate species being transported in this way He adds that when fairly out at sea the mosquito visitors which invaded the ship in cheerful numbers while in dock rapidly diminished and eventually disappeared. There is no doubt that even the most tender insects can often fly much further than is generally supposed—witness, for instance, the migrations of various butterflies. But even granting the strength of wind sufficient to convey a mosquito across an arm of the sea the passage would be impossible. As the author acutely points out, the very fact that sunlight is fatal to its well being would prevent such an excursion and the possible and consequent stocking of a new country with these diptera. Nor can the mosquito overcome the difficulty of transport by voyaging willy nilly in the larval stage. Lieutenant-Colonel Giles quotes Professor Celli to the effect that the young of anopheles died in 13 hours in salt water and that even brackish water was fatal with comparative rapidity That mosquito larvæ haunt marshes of a saline character has been often asserted but apparently on but slender grounds. In short carriage by land is the only way in which a mosquito can extend its range. It is often pointed out and probably most persons who know anything about the matter at all think, that the genus anopheles is to be distinguished from culex by its habit of standing on its head so to speak when at rest. This is another common fallacy which the author disposes of; his observations upon a new specimen of anopheles seem to show that this acrobatic mode of resting is not peculiar to that genus.

But here we must take our leave of this work which certainly contains much of interest and something of novelty. If the author had been better supported by his publishers in the way of "get up" we should have predicted a considerable circulation for this epitome of the structure and classification of mosquitoes.

Encyclopædia Medica. Under the general editorship of D. CHALMERS WATSON, M.B., F.R.C.P. Edin. Vol. IX. Osteo-arthropathies to Pregnancy (Physiology). Edinburgh: William Green and Sons. 1901. Pp. 518. Price 20s.

THE first contribution of importance in this volume is one on Diseases of the Ovaries, by Mr. Alban H. G. Doran. Brief remarks are made on the common affections of the ovary, and tumours of that organ are also described. The comments on ovarian cysts are well worthy of attention; an excellent description is given of the anatomy of the capsules, a knowledge of which is of high importance to the surgeon.

Dr. J. W. B. Hodsdon, assistant surgeon to the Royal Infirmary, Edinburgh, writes on Injuries and Diseases of the Palate and Hare-lip. He gives a good account of the operative procedures which are necessary for the relief of cleft palate, not forgetting the after-treatment in the way of training the voice. Much care and patience are required to enable the patient to speak properly and two main objects have to be obtained: to develop the muscles of the palate by exercises and to correct the faulty habit of speech.

The Physiology of the Pancreas is described by Dr. J. A. Milroy, late demonstrator of physiology, Yorkshire College, Leeds; whilst Mr. A. W. Mayo Robson, senior surgeon, Leeds General Infirmary, is responsible for the article on diseases of that organ. Mr. Robson believes chronic pancreatitis to be a much more common affection than are the acute and subacute forms and he has no doubt that some cases diagnosed as malignant disease of the head of the pancreas and terminating fatally are cases of chronic interstitial pancreatitis.

The subject of Paralysis is divided between three authors—Dr. J. S. Risien Russell, Dr. Frederick E. Batten, and Dr. James S. Collier. The present section deals with the so-called systemic lesions of the cord and other diseases of the grey and white matter. Descriptions are given of spastic paraplegia and infantile spastic paralysis, of family periodic paralysis, and of Landry's paralysis (acute ascending paralysis). Further, accounts are given of the forms of paralysis accompanied with atrophy of muscles. These include acute anterior poliomyelitis, subacute anterior poliomyelitis, chronic spinal muscular atrophy, and bulbar paralysis. Then follow those forms of paralysis characterised by tremor or ataxy—disseminated sclerosis, pseudo-sclerosis, paralysis agitans, and hereditary ataxia. Finally, functional paralysis is considered. These subjects would in themselves yield material for a large volume and consequently in this publication a description of them has to be rather condensed. The authors, however, have performed their task well and have given a vast amount of information in a comparatively small space.

Under the heading of Parasites Dr. W. T. Ritchie of Edinburgh contributes an article on Animal Parasites. He adopts the usual classification—protozoa, helminths, and arthropods—and for purposes of reference Dr. Ritchie's remarks will be found useful.

Dr. W. E. Fothergill of Manchester writes on the Anatomy of the Perineum and Pelvic Floor and Dr. F. W. N. Haultain on Diseases of the Peritoneum and Cellular Tissue of the Pelvis. The general description of the peritoneum is by Mrs. Garrett Anderson, Mr. H. P. Dean writing on Acute Peritonitis and Mr. D'Arcy Power on Tuberculous and other Affections of the Peritoneum.

Dr. J. A. Lindsay, professor of medicine, Queen's College, Belfast, describes the Medical Affections of the Pleura. He rightly speaks with caution on the pathology of diseases of the pleura and concludes that this part of the subject (especially the bacteriology) must be submitted to a rigid criticism and interpreted in the light of the facts of clinical experience before satisfactory conclusions can be arrived at. The Surgery of the Pleura is dealt with by Dr. T. Sinclair, professor of surgery, Queen's College, Belfast. The subject of Pneumonia is also divided into two sections, the bacteriology being considered by Dr. D. A. Welsh, pathologist to the Royal Infirmary, Edinburgh, and the clinical aspect of the disease being described by Sir J. W. Moore, Professor of Practice of Medicine, Royal College of Surgeons in Ireland. The remarks on treatment are worthy of careful attention.

The subject of Pregnancy is divided into four sections: (1) Changes in the Maternal Organism, by Dr. J. Lamond Lackie, gynæcological tutor, Royal Infirmary, Edinburgh; (2) Diagnosis of Pregnancy, by Dr. W. Fordyce, assistant physician, Royal Maternity Hospital, Edinburgh; (3) Multiple Pregnancy, by Dr. W. Stephenson, professor of midwifery, Aberdeen University; and (4) Management of Pregnancy, by Mrs. Chalmers Watson, M.D. Edin., senior assistant physician, Edinburgh Hospital for Women and Children.

There are many other contributions to this volume which add to its value but we have not space to comment on them. Suffice it to say that the standard of the publication is efficiently maintained, rendering the Encyclopædia a most useful work of reference.

A Laboratory Guide in Elementary Bacteriology. By WILLIAM DODGE FROST, M.S., Instructor in Bacteriology, University of Wisconsin. Second revised edition. Illustrated. Madison, Wis.: published by the Author. 1902. Pp. 355.

THIS work represents substantially the course of practical instruction given to the students of bacteriology at the University of Wisconsin. Its popularity is evidenced by the call for a second edition within a year of its first appearance, and the character of the instruction furnished by the book certainly justifies this appreciation. The course is divided into two parts, treating respectively of general and medical bacteriology. The latter is evidently not intended to stand by itself but it is assumed that the course of general bacteriology has been previously carefully studied. The instructions are divided into a series of short "exercises" in such a way as to make it comparatively easy to adapt the course to the varying requirements of different laboratories and different classes of students. There is some lack of courage, though less in this book than in many, in deciding whether the work is to stand alone as a complete laboratory guide or to be supplemented by demonstrations; consequently the instructions are in places too short for the first alternative and too long if the aid of a demonstrator is presupposed.

The general course begins with the study of morphology and elementary technique, passes on to the physiology of bacteria, then to a systematic study of representative non-pathogenic bacteria, and finally to the analysis of air, water, and milk and the action of antiseptics. The medical part of the course commences with the study of the principal pathogenic bacteria, followed by the methods of bacteriological diagnosis and the examination of water and milk for pathogenic germs. A characteristic feature of the book is the provision of a number of blank forms to be filled by the student with details of the morphological, cultural, chemical, and other characters of the organisms studied. If conscientiously carried out the method should be of considerable educational value. In some details the instruction might be improved The valuable hanging drop culture is dismissed with insufficient details as to sterilisation and with no reference to any medium save agar The dried drop method of collecting blood for Widal s reaction is alone described and the bacteriological diagnosis of cholera occupies only nine lines. In the differential diagnosis of bacillus diphtheriæ no mention is made of the acid production in glucose broth (Cobbett) There is a curious misprint of ' military tuberculosis" (p. 326) and Professor Delépine s name is also transformed (p. 301) On pagé 36 a magnification of 2500 diameters is said to be represented thus × 2000 These are however small blemishes in an otherwise excellent text-book which bears the impress of having been practically tested in the laboratory A most excellent series of laboratory rules is prefixed.

Morphinism and Narcomanias from other Drugs By T D CROTHERS M.D Superintendent of Walnut Lodge Hospital Hartford Conn U S A. Editor of the *Journal of Inebriety* London and Philadelphia W B. Saunders and Co 1902. Pp 351. Price 9s net.

DR. CROTHERS has long been known for his work in connexion with the nervous and mental affections associated with alcoholic and other drug habits and as medical superintendent for many years of an institution devoted to the care and treatment of patients suffering from such affections in the United States his experience has been large and varied. The present work is really a general preliminary survey of the subject of morphinism and of the nervous and mental troubles arising from drug habits generally All modern writers says Dr Crothers recognise the growth of these habits and vices, and it is stated that in the United States the sale of morphine in some large cities indicates that not one-half of the amount sold is traceable to the legitimate demands of physicians and hospitals. Dr Crothers quotes statistics and figures from a great variety of sources to show that the morphia habit is becoming largely prevalent among medical men in France Germany and the United States. The first 220 pages of the book are devoted to an excellent account of the various causes symptoms and stages of morphinism the discussion being throughout illuminated by an abundance of facts of clinical, psychological and social interest. The complication of this vice with other drug habits is lucidly sketched and a concise description is given of the treatment adopted at asylums and retreats for the reception and treatment of patients thus affected The medico-legal aspects of morphinomania in regard to criminality responsibility and competence to give evidence in a court of law are discussed and sound canons are laid down for the guidance of the physician in reference to such matters. Other forms of drug habits are then taken up and dealt with *seriatim*—viz cocainism chloralism chloroformism tobacco inebriety etherism the sulphonal and trional habit and the consumption of tinctures such as those of lavender Jamaica ginger and the like which are largely composed of crude forms of spirits The book is written throughout in an easy and somewhat popular style and appeals to the general reader as well as to those specially interested in the subject as regards its medical and sociological aspects

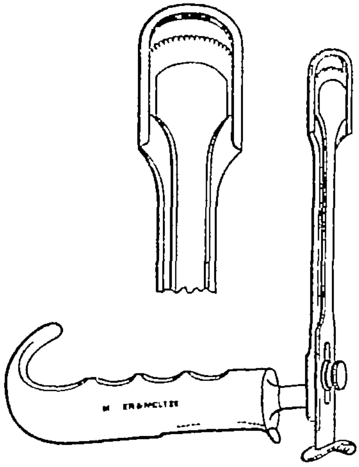
JOURNALS AND MAGAZINES

The Medical Magazine — The Inebriate Acts, 1879–98, in their Relation to Inebriety is the title of a paper by Dr Edward Norton which comprises the chief interest of the current number of this journal Dr Norton shows that although the number of persons seeking treatment in institutions is still far smaller than is desirable considering the number to whom such treatment is really applicable, yet there has been for 20 years a steadily maintained increase in the number of applicants. He is of opinion that good industrial retreats for destitute inebriates, scattered throughout the country and supported by the results of the patients own labours by local authorities and by voluntary aid, are within the range of practical politics. We agree.

New Inventions.

THE ANATOMICAL TONSILLOTOME.

THE orifice for the reception of the tonsil in this instrument is made to correspond to it in shape being oval with the long axis vertical By this means the hypertrophied tonsil can be much more completely excised and not merely clipped as is usual with the tonsillotomes most employed. Another advantage is that the lowest point of enlargement is removed and not left to keep up irritation and cough as is commonly seen when the oval tonsil is squeezed into a round or horizontally elongated orifice. The second modification consists in the serration of the blade. This has a marked effect in lessening hæmorrhage especially in adults as the tonsil is lacerated rather than sharply incised. The third new feature is that the handle is not only massive having indentations for the *fingers and thumb affording greater* grasping surface and power but that it is prolonged into a hook at the end. The advantage of this is that the operator by utilising the ulnar side of the hand has much increased power for levering outwards and thus pressing well over the tonsillar base just before driving the blade home. For the excision of large flat adult tonsils these modifications are invaluable and render this instrument a safe and efficient substitute for the slow clumsy and imperfect methods of the écraseur *morcellement* and enucleation



Welbeck-street W WM STUART LOW F R.C S Eng

ROYAL ALBERT HOSPITAL, DEVONPORT —A very successful fête was held on June 26th 27th and 29th at the Exhibition grounds Devonport, in aid of the funds of the Royal Albert Hospital To maintain this institution about £4000 are needed annually but unfortunately the annual excess of expenditure over receipts is about £1300 and the fête has been organised with the object of meeting this deficit

THE LANCET.

LONDON SATURDAY, JULY 5, 1902

The Illness of the King

WE are exceedingly glad to be able to state that His Majesty the KING is progressing well. It has been necessary to remove the drainage tubes as they could not be tolerated and gauze plugs are now used instead. The wound is granulating satisfactorily and the discharge has diminished and is perfectly inodorous. The KING suffers less, and although the dressings are still necessarily painful His Majesty bears the process with the utmost courage. His temperature has been normal since Thursday, June 26th It will, we are sure, afford the greatest satisfaction to his subjects throughout the Empire to know that the condition of the constitution of the illustrious patient is admirable He is, moreover, an extremely good patient and is absolutely loyal to his medical attendants All these things, we hope, bode well for his restoration to health at no very distant date

---

THE present condition of His Majesty the KING and the future progress of his health can be gauged best by a full consideration of the case from the very beginning Our readers will be able to follow the thread of our remarks if they read in connexion with them the brief account of His Majesty's illness which appeared in our second edition last week and which we reprint below Firstly, was there any condition present which might predispose to the development of perityphlitis? Although no reference appears to have been made to it it is far from unlikely that the severe attack of typhoid fever from which the KING suffered in 1871 may have had some etiological connexion with his present illness The ulceration of the bowel in typhoid fever is especially severe near the ileo cæcal valve and adhesions occurring as a result of the intestinal ulceration, especially when the attack has been prolonged, are not uncommon. Adhesions of this nature are liable to produce displacement and torsion in the neighbourhood of the cæcum, and it is now recognised that in this way the circulation may be distinctly interfered with, and that such disturbances of position and circulation are important predisposing causes in the production of perityphlitis. So that it is quite possible that the attack of enteric fever from which the KING suffered more than 30 years ago may be really connected with the illness from which he is suffering now

The present attack appears to date from some 10 days earlier than the operation For it was on June 14th that the KING first complained of abdominal discomfort, but it was slight and did not interfere with the journey to Aldershot. At midnight of the same day abdominal pain came on, and SIR FRANCIS LAKING was summoned and was able to relieve the urgency of the symptoms, and on the next day, June 15th, His Majesty was seen by SIR THOMAS BARLOW Up to this time the signs and symptoms were indefinite, and though they were sufficient to suggest the possibility of perityphlitis, no trustworthy diagnosis could be made On the afternoon of the 15th a chilly fit occurred, this was in all probability a real rigor and marks the time at which from the after history of the case we may conclude that suppuration commenced We may interpret these symptoms by the light of our later knowledge as follows the commencement of the perityphlitis dates from the first abdominal discomfort of which the KING complained on Saturday, June 14th It may have been connected with the great fatigue of the previous day and the taking of a late supper, but it is quite possible that neither had anything to do with it. During Saturday and Sunday the inflammation extended and set up an adhesive peritonitis To this was doubtless due most of the pain of which the KING complained. Then pus began to form around the cæcum This suppuration was loca by the adhesions which had already formed betw the adjoining coils of intestine, and if our suggest be correct as to the influence of the attack of typh fever old adhesions remaining from that illness m have assisted in confining the suppurative process B Monday, June 16th, the KING had recovered sufficientl to bear well the drive to Windsor, for he arrived there without fatigue On the Tuesday signs began to appear which rendered certain the nature of the affection, and when he was seen on Wednesday, June 18th, the local manifestations were well marked In the right iliac fossa there was an ill defined, somewhat firm swelling, with distinct tenderness but no very marked pain independently of pressure. The temperature was raised and the diagnosis could be made with ease and certainty Then would arise the question of operation There are some in this country, and still more abroad, who advocate operative measures at the earliest possible moment, but by indiscriminate operation in all cases without regard to the exact nature of the local condition the best results are not obtained. It cannot be disputed that a large number of cases of perityphlitis recover without surgical aid and that many others result in the formation of a localised abscess which may be evacuated without necessarily disturbing the cæcum, without indeed it ever being established that inflammation in its vicinity was the cause of the trouble. The great danger in perityphlitis is general septic peritonitis What may be called the "natural" method of prevention of this complication is by the formation of peritoneal adhesions, shutting off the focus of infection from the rest of the peritoneal cavity To attempt to disturb the cæcum while this process of localisation of the suppuration is going on can only lead to the hastening of the evil which it is desired to avert, for the breaking down of the protective adhesions will almost certainly cause the generalisation of the peritoneal infection There is the less need to discuss the question of the superiority of early or late operation seeing that we have no proof in the KING's case that the appendix was inflamed, but we may be permitted to express our complete approval of the course adopted by His Majesty's medical advisers

With complete rest on Thursday, Friday, and Saturday the

KING'S condition improved the temperature fell to normal and he felt better in himself and the improvement continued during the Sunday so that on Monday His Majesty was able to journey to London by train. Up to Monday, June 23rd it had been hoped that care and rest had served the patient so well that the necessity for active surgical treatment had passed away This was only in accord with the earnest wish of the KING who was extremely anxious to carry out at whatever pain to himself the arrangements that had been made. On Monday however the probability of the presence of pus in the right iliac fossa was suspected and on the morning of Tuesday June 24th, it became clear that suppuration had occurred. The iliac swelling was again obvious the pain had increased, and the temperature was once more elevated. All these signs pointed clearly to the formation of a localised abscess. The danger of delay was great. The formation of pus was evidently proceeding rapidly and the abscess was extending In such circumstances the impossibility of sanctioning any attempt at carrying out the Coronation ceremony was at once obvious Nay more, the necessity for the immediate evacuation of the pus was urgent, for if no outlet for it were provided the far greater danger of general septic peritonitis was imminent, a condition in which surgical interference is too often of small avail Lord LISTER and Sir THOMAS SMITH agreed that an operation was imperative and the KING gave his assent reluctantly not because of the pain or the risk to himself but because he knew the severe disappointment the change of plan would occasion to the many thousands who were assembling in honour of his Coronation.

To Sir FREDERICK TREVES was committed the heavy responsibility of performing the operation. An incision was made a short distance above Poupart's ligament on the right side the wound was steadily deepened but it was not until it had obtained a depth of some four and a half inches that pus was reached This was evacuated and the abscess cavity was drained by means of two rubber tubes. By the evacuation of the pus and the subsequent drainage the immediate risk of the involvement of the general peritoneal cavity was averted and thus the danger of the disease was greatly reduced The effects of the operation soon showed themselves. The pain from which the patient had suffered severely was markedly relieved, the temperature rapidly fell and it was evident that the septic absorption had ceased. It was possible for his medical attendants to announce on the same evening that the KING'S condition was as good as could be expected after so serious an operation, that his strength was well maintained, and that the pain had diminished There was an addendum to the effect that it would be some days before it could be said that the KING was out of danger, this was a necessary warning to the public, for it may happen that the extension of the suppurative process does not cease with the evacuation of the pus.

During the earlier part of the first night after the operation His Majesty was restless and did not sleep but after one o'clock some sleep was obtained. A fairly comfortable day followed and but little pain was experienced except at the dressing of the wound. His strength was fairly well maintained. On the second night he had some refreshing sleep and he improved in all respects and the state of the wound continued satisfactory On Friday June 27th, it was announced that a fair night had been passed and that the temperature remained normal. On Sunday the fifth day after the operation, the KING was sufficiently recovered to permit his being moved on to a couch for a few hours, and up to the time of writing the improvement has steadily continued. A fair amount of sleep is obtained the KING'S strength increases and the wound continues to progress in a satisfactory manner It is, of course, most important that the abscess cavity should close completely and from the bottom, otherwise an intractable sinus would be not unlikely to result. The wound is therefore packed with gauze and this necessarily occasions no small amount of pain. This is unfortunate but cannot be avoided and it is consoling to remember that the pain will decrease with each dressing

We have followed the illustrious patient's progress from the commencement of his illness to the present time and we are now in a position to consider the prognosis. The dangers which may arise may proceed from the patient's constitution or be connected with the local lesion. As to the KING'S general constitution there is but little cause for anxiety At his age, 61 years he is probably as strong as the average of his subjects and apart from the harassing nature of his duties and the energy and zeal with which he has ever undertaken all that he is called upon to do there has been nothing materially to impair his general health The severe attack of typhoid fever in 1871, to which we have already alluded served for a time to weaken him but the effect was transient. It cannot however be doubted that the grave disappointment which the KING feels at having to postpone the Coronation may exert some depressing effect on him To dispel as far as possible any untoward mental or sentimental condition must be the best endeavour of those around his bedside. Turning to the local conditions we find several possibilities of harm. The wall of the abscess cavity is formed by coils of small intestine which have become adherent owing to adhesive peritonitis some of these adhesions have probably already commenced to organise. Somewhere in this wall there may be a peccant appendix matted to the intestine by exuded lymph from it and from the other parts of the wall of the abscess cavity pus may be still secreted. The chief danger is the extension of the suppurative process to the general peritoneal cavity but day by day the adhesions localising the mischief are growing stronger organisation proceeds rapidly and before long they will be strong enough to resist any strain to which they may be subjected. The danger from this cause has steadily grown less and less with every favourable bulletin. Again the risk of the absorption of septic products from the abscess cavity is now very small as all tension has been removed and the granulations which have formed offer an effective resistance to the passage of the toxins into the blood vessels and lymphatics at any rate, the state of the temperature shows that now no absorption is taking place. The chance of the occurrence of general septicæmia may be disregarded. On a critical review of the situation of the KING it may be said that there is great promise of a speedy and safe recovery from his illness, speedy we say though many weeks must elapse before he is well, for we must bear in mind the severity of the illness and of the operation performed for its relief, and safe because the probability of any complication supervening is remote. On the maintenance of his strength, apart from care in dressing the wound, depends mainly the recovery of His Majesty.

One further point requires consideration. If, as we may not unreasonably hope and expect, the KING recovers from his illness, will a recurrence be likely or will it ever be necessary to interfere with the appendix? The answer which would be given by those surgeons who have had most experience in abdominal surgery would surely be "No." When an abscess has developed in connexion with the appendix and has been successfully drained it is rare, indeed, for any recrudescence of mischief or for any further operation to be required.

THE following account of His Majesty's illness appeared in the second edition of THE LANCET, published on Wednesday, June 25th:—

We were able to state yesterday, June 24th, that an abdominal operation had been successfully performed on His Majesty by Sir FREDERICK TREVES on that morning. The anæsthetic was administered by Dr. FREDERIC HEWITT and was borne well, His Majesty recovering consciousness without any ill effects whatever. The operation was attended by no complications; a large abscess was found and evacuated. To-day, June 25th, we are able to give the following account of his illness.

We give this account of His Majesty's illness and purposely do so in the briefest and plainest terms, because we know that although our statement will primarily be read by our medical readers it is certain to reach the public, and it seems to us at the present juncture that it is highly important that the public should know the real state of the case. We may preface our remarks by saying that while it is impossible to disguise the serious nature of the KING'S condition it is also our joyful privilege to be able to contradict flatly some of the sinister rumours that during the last 48 hours have been prevalent throughout the world.

On Friday, June 13th, His Majesty the KING towards the evening was suffering from great fatigue. After attending the Court and the many arduous duties of the day, he had a late supper and went to bed, and on the following morning, Saturday, June 14th, he complained of abdominal discomfort. His Majesty was seen during the day by Sir FRANCIS LAKING, Physician in Ordinary to the KING and Apothecary to the Household. In the afternoon he was distinctly better. He then left for Aldershot where he dined with the QUEEN, being present in the evening at a "tattoo" held under unfortunate atmospheric conditions. On Saturday at midnight he complained of abdominal pain and a feeling of distension. Sir FRANCIS LAKING was sent for and arrived at Aldershot at a quarter to five in the morning. Remedies were administered and the symptoms were all relieved. It may be added that no morphia was given. But Sir FRANCIS LAKING, recognising the presence of an abdominal trouble that might be serious, telegraphed for Sir THOMAS BARLOW, Physician to the Household, who arrived on Sunday, the 15th, and stayed there during the day. On the afternoon of Sunday His Majesty had a chilly fit which in all probability amounted to a rigor. On the following day, Monday, the 16th, he proceeded in a carriage to Windsor, adopting this method of travelling by his physicians' advice, for it was felt by his medical advisers that if, unfortunately, his symptoms should develop for the worse it would be much better that he should be in his own home. The journey was made in comfortable circumstances, he bore it well, and felt better at the end of it. On Tuesday, the 17th, recognising that, in view of the approaching Coronation, no physical labour which could possibly be avoided should be undertaken, His Majesty reluctantly abandoned the idea of being present at Ascot. He remained recumbent most of the day but drove for three quarters of an hour in the private grounds attached to the Castle.

On Wednesday, the 18th, His Majesty was seen by Sir FREDERICK TREVES, and this point in the clinical history of his disease is one of the highest interest to medical men. The temperature was then elevated, there were swelling and tenderness in the right iliac fossa—in short, there were symptoms of perityphlitis. But during the following Thursday and Friday all these ominous symptoms disappeared. When Sir FREDERICK TREVES saw His Majesty on Saturday, the 21st, his temperature had fallen and had been normal for two and a half days, the swelling in the iliac region had nearly vanished, and in every way the KING was much better. It was then believed that the KING was on the road to rapid recovery, and that he would be able to go through the Coronation ceremonies. Sunday, the 22nd, was uneventful, and on Monday, the 23rd, the KING travelled from Windsor to London, his entrance to the capital being received by the public as a proof that they need attach no credence to any of the many alarming rumours that had now become widespread. The KING made the journey by railway. On his arrival the KING saw Sir FREDERICK TREVES again and at this period His Majesty's medical and surgical advisers began to be suspicious that there might be pus in the right iliac region.

Next day the necessity for operation became clear. At 10 o'clock on Tuesday morning the urgency of an operation was explained to His Majesty, and recognising that his ardent hope that the Coronation arrangements would not be upset must be disappointed he cheerfully resigned himself to the inevitable. Before the actual decision upon operation was arrived at Sir FREDERICK TREVES, Serjeant-Surgeon to the KING, took the advice of the two other Serjeant-Surgeons, Lord LISTER and Sir THOMAS SMITH, and they, as well as Sir THOMAS BARLOW and Sir FRANCIS LAKING, came to the unanimous conclusion that no course but operation was possible in all the circumstances. To delay would, in fact, be to allow His Majesty to risk his life. At 12.30 on Tuesday, the 24th, the operation was performed by Sir FREDERICK TREVES, and concerning this there is very little to add to what we have already said. The KING was placed under an anæsthetic by Dr. FREDERIC HEWITT, anæsthetist to His Majesty, an incision was made by Sir FREDERICK TREVES in the usual place, and a large abscess was opened. The incision was four and a half inches deep and some decomposed pus was evacuated The cavity was drained by two tubes of large calibre and packed with iodoform gauze.

Such is the brief clinical history of His Majesty's illness and only one or two comments are necessary from us to enable the public to understand the position It will be seen that the story makes the bulletins completely clear and shows them to be exactly accurate The idea that some dreadful news is being kept back ought, we think, to be dispelled.

Firstly the KING in his illness has throughout been advised by his proper medical attendants. When Sir FRANCIS LAKING Apothecary to the Household and Physician in Ordinary to the KING desired a consultation Sir THOMAS BARLOW, Physician to the Household was sent for When a surgical opinion was necessary in view of unfortunate developments Sir FREDERICK TREVES, Serjeant-Surgeon to His Majesty, was called in to consultation When he and the two physicians recognised the urgency of His Majesty's symptoms the two other Serjeant-Surgeons to the KING Lord LISTER and Sir THOMAS SMITH were summoned to express an opinion before the last critical step was taken.

The second point to which we would call attention is the absolute sincerity of every bulletin that has been issued for this sincerity it seems to us, should prevent the public from giving heed to the wild rumours now rife. His Majesty is suffering from perityphlitis and nothing else. It is an unfortunate fact with regard to perityphlitis as all our readers know that the symptoms may for various reasons be entirely masked This it was that absolutely prevented the necessity for operation being apparent until the Tuesday before the Coronation

There was no symptom of malignancy present.

◆

The Daily Press and the Illness of the King

THE news of His Majesty s illness naturally created widespread interest and the daily press in its anxiety to give read every information discharged its duties to its readers th accuracy on the whole. Especially was this the case where the clear and adequate bulletins were carefully followed mastered and used as texts for exposition Still, a few extraordinary statements require a word or two of comment from us. Nearly all the papers, apparently on the authority of the *Press Association* stated that the trouble took the form of an intestinal abscess the growth of which blocked the natural channel. The obstruction having been excised a system of tubing was resorted to to make the intestine available for its natural functions. The confusion here expressed between a drainage-tube and a Murphy's button is perhaps natural in a layman s mind and the information upon which the paragraph was founded could only have come from an ignorant person But the result of the publication of this paragraph was to give a very sinister complexion to the KING S illness, for an excision of a portion of the intestine was clearly implied. Our simultaneous statement that the operation was attended by no complications served we have been informed to modify that impression. More than one paper waxed learned about the stitching up of the wound, attaching importance to the day or hour when the stitches would be removed and basing prophecy thereon the would be medical writers not seeing that, of course, the wound was not closed the exact medical description of the dressings employed conveying nothing to them In the *Westminster Gazette* an eminent surgical authority fell into this obvious blunder and caused this carefully-edited evening paper to mislead its many readers in a mischievous way We do not think that Mr HARRISON CRIPPS will approve of the manner in which the *Westminster Gazette* quoted his book in support of a treatment which has not been and could not be followed. The most amazing error however appeared in the *Daily News* of June 25th. It purported to be a medical practitioner s view" and began as follows —

> Perityphlitis," said our professional informant is inflammation of the tissues surrounding the kidney—round about the kidney in contradistinction to inflammation of the kidneys—and it is extremely difficult to say till the operation has taken place whether the case is perityphlitis or is inflammation of the kidney itself "

Then followed a hopelessly tangled and muddled set of statements concerning an operation for calculus of the kidney While publishing this statement upon the authority of a member of the medical profession of high standing the *Daily News* seems to have felt that there was something wrong and so a second medical man was applied to This gentleman was not quite so much at sea as the first one for he did associate perityphlitis with the intestine and not with the kidney but when he went into details he lost himself. It is difficult to believe that the rubbish published by the *Daily News* was written by a medical man and we simply cannot understand how it came to be published One paper our excellent contemporary the *World* has earned an official contradiction that has not been granted to less important periodicals. A highly ludicrous picture of the operation given in its columns on Wednesday last, July 2nd, has been pilloried as entirely inaccurate," and again it is impossible to understand how such a description could have been published in the face of the bulletins and the statements in our columns and those of the *British Medical Journal*

◆

The Coronation Honours

THE Coronation honours which were made public on Thursday the day appointed for the ceremony so unavoidably postponed are of particular interest to medical readers. This is so not only because of the large number of our profession whose services have been found worthy of recognition on the occasion which was intended to be the official commencement of the reign of King EDWARD VII. but because the general design of the Crown, and of the advisers of the Crown, appears to have been to do ample justice to workers in the cause of humanity at large. The honours have been distributed in accordance with a broad and generous conception of the character of the labour that has been for the good of the generation and not exclusively as rewards for party or administrative zeal. This fact is well displayed by the new Order which His Majesty has been pleased to institute—viz. the *Order of Merit and to which the following appointments have been made* —Field Marshal Earl ROBERTS of KANDAHAR, K.G K.P V C Field Marshal

Viscount WOLSELEY, K.P., G.C.B., General Viscount KITCHENER of KHARTOUM, G.C.B., G.C.M.G., Lord RAYLEIGH, F.R.S., Lord KELVIN, G.C.V.O., F.R.S., Lord LISTER, F.R.S. Admiral of the Fleet the Honourable Sir HENRY KEPPEL, G.C.B., the Right Honourable JOHN MORLEY, M.P., the Right Honourable W. E. H. LECKY, M.P., Admiral Sir EDWARD HOBART SEYMOUR, G.C.B., Sir WILLIAM HUGGINS, K.C.B., P.R.S., and GEORGE FREDERICK WATTS, R.A. All our readers will rejoice to find among the 12 men first selected for the new honour Lord LISTER, Lord KELVIN, Sir WILLIAM HUGGINS, and Lord RAYLEIGH, for it is deeply gratifying to men of a scientific profession to find three Presidents of the Royal Society and a fourth who is an inevitable holder of that post in so select a list—a list obviously intended to classify those mentioned as the very salt of His Majesty's subjects. The work done by this small band of men is so historic in its character that it needs no particularising from us, but we may be permitted to offer our special congratulations to Lord LISTER, the father of modern surgery. Lord LISTER has also been made a member of the Privy Council—a distinction which we believe has never been previously conferred upon any medical man save the late Professor HUXLEY.

The KING has been pleased to confer baronetcies upon two members of the medical profession—Sir FRANCIS LAKING, K.C.V.O., Physician in Ordinary to His Majesty, and Sir FREDERICK TREVES, K.C.V.O., C.B., Honorary Serjeant-Surgeon to His Majesty. The position these two gentlemen occupy now at His Majesty's bedside invests their honours with interest. The whole list of knighthoods is not a very large one taking all the circumstances into consideration so that the number of medical men selected for this distinction is in proportion a goodly one. His Majesty has been pleased to confer the honour of knighthood upon Dr. W. J. COLLINS, an ex chairman of the London County Council, a Radical of the advanced school, and an able surgeon; Mr. ALFRED COOPER, a member of the Council of the Royal College of Surgeons of England; Dr. J. HALLIDAY CROOM, President of the Royal College of Surgeons of Edinburgh; Dr. THOMAS R. FRASER, F.R.S., President of the Royal College of Physicians of Edinburgh, whose work in connexion with the Indian Plague Commission and with the poison of serpents has made his name justly prominent; Mr. VICTOR HORSLEY, F.R.S. whose neurological labours rather than his medico political labours are probably being rewarded, but who has striven for the good of his professional colleagues with a courage and vigour that will lead them all to rejoice in his knighthood; Mr. H. G. HOWSE, President of the Royal College of Surgeons of England and Senior Surgeon to Guy's Hospital; Mr. HENRY BELL LONGHURST, Honorary Surgeon Dentist to His Majesty; Professor WILLIAM MACEWEN, F.R.S., Regius Professor of Surgery in the University of Glasgow, and a pioneer in the modern surgery of the brain and spinal cord; Dr. THOMAS MYLES, the President of the Royal College of Surgeons in Ireland; Dr. ISAMBARD OWEN, Senior Deputy Chancellor of the University of Wales, who is also physician to, and the urbane and energetic Dean of, St. George's Hospital; and Professor WILLIAM WHITLA of Belfast, the brilliant pharmacologist, the generous donor of the medical institute to the Ulster Medical Society, and, we believe, the first Belfast medical man to receive a title. Another medical man, Dr. CONAN DOYLE, the well known author, has been knighted, the honour coming as a testimony to the value of his national services in chronicling the story of the great war now so happily closed and in correcting foreign misstatements and misapprehensions concerning the British attitude before, and conduct during, martial operations. We also have to congratulate on the occasion of their knighthood Professor OLIVER LODGE, F.R.S., the Principal of the Birmingham University; Professor ARTHUR RÜCKER, F.R.S., the Principal of the University of London; Mr. W. J. SOULSBY, C.B., C.I.E., secretary now, as on many previous occasions, to the Lord Mayor of London and a tireless worker in many charitable causes; and Mr. CHARLES WYNDHAM, the popular and admirable actor who, more than 30 years ago, before adopting his present calling, was a member of our profession, obtaining a medical degree and serving in a medical capacity in the American civil war.

In divisions of the different Orders the names of many medical men will be found. Sir WILLIAM CHURCH, Bart., President of the Royal College of Physicians of London, has been appointed a Knight Commander of the Bath (Civil Division), while in the Military Division of the same Order will be found the names of Inspector General of Hospitals and Fleets J. D. MACDONALD, R.N., Professor WILLIAM RAMSAY, the eminent chemist, Surgeon-General ANNESLEY C. C. DE RENZY, I.M.S. (retired), Surgeon General (ranking as Lieutenant-General) WILLIAM TAYLOR, Director General of the Army Medical Service; and Surgeon General JOHN A. WOOLFRYES, C.M.G. Among the new Companions of the Bath (Civil Division) will be found the names of Major RONALD ROSS, F.R.S., I.M.S. (retired), who has worked day and night that some of the malarious possessions of the Crown may benefit by the discoveries, in which he himself played no small part, as to the etiology of malaria; of Dr. B. ARTHUR WHITELEGGE, His Majesty's Chief Inspector of Factories, whose official and medical work have alike brought him credit; of Dr. DUNCAN HILSTON and Dr. ROBERT GRANT, who both hold the rank of inspector general of hospitals and fleets; of Lieutenant-Colonel Sir JAMES R. A. CLARK, Medical Staff Corps, the eldest son of the late Sir ANDREW CLARK; and of Lieutenant-Colonel G. T. BEATSON, Medical Staff Corps. Two medical men are made Companions of the Bath (military division)—viz., Fleet-Surgeon JAMES PORTER and Lieutenant Colonel PATRICK F. O'CONNOR, I.M.S. Two medical men have been appointed Knights Commanders of the Order of St. Michael and St. George—viz., the Hon. Dr. FREDERICK W. BORDEN, Minister of Militia and Defence of the Dominion of Canada, and Surgeon General H. H. PINCHING, head of the Sanitary Department at Cairo. Dr. HO KAI has been appointed a Companion of this Order. The KING has granted the Kaisar-I-Hind medal for public service in India to the following gentlemen among others: Captain T. W. A. FULLERTON, I.M.S., Lieutenant-Colonel JOHN LEOPOLD POYNDER, I.M.S., and Mr. EDGAR THURSTON, L.R.C.P., superintendent Government Central Museum, Madras. A list of naval and military honours, so far as they affect the medical departments, will be found in the columns of this issue of THE LANCET under the heading of The Services ', and this list completes a total of distinctions received by our profession that is gratifying to contemplate.

Annotations

' Ne quid nimis."

THE IMPERIAL VACCINATION LEAGUE

VACCINATION is a procedure of undoubted value. But proportionately to its value it has aroused bitter opposition and although for the most part its detractors are men and women of no intellectual calibre who are moreover absolutely ignorant of pathology yet on the well known principle that if enough mud is thrown some of it will stick the fact remains that vaccination is unwelcome to a large number of persons. The Jenner Society has done, and is doing excellent work but its provincial position in some ways hinders its usefulness. The Imperial Vaccination League which has been developed from the league started last year by Mr John Carrington will work in alliance with the Jenner Society which will remain to carry on its good work in Gloucester and to keep Jenner's memory green in that city and its neighbourhood. The Imperial League which was formally constituted on June 30th has for its president the Duke of Fife. The treasurer is Lord Avebury and among the vice presidents are the Archbishop of Canterbury the Bishops of London, Rochester and Stepney Cardinal Vaughan the Chief Rabbi, Sir W Broadbent, Sir James Crichton Browne Mr Jonathan Hutchinson, and Mr Claude Montefiore. The provisional committee consists of Dr J C Thresh, Dr J G Glover Dr T D Acland Dr Dudfield Mr R. Brudenell Carter Dr E. Garrett Anderson the Revd. H. L. Paget, Mr John Carrington, and Mr. Greenwood The league will at present aim at collecting opinions as to what amendments of the Vaccination Act of 1898 may be urged upon the Government when the time comes for dealing with the subject, and among the most important points for consideration the promoters of the league include —

(a) Whether revaccination at school age should be made obligatory

(b) Whether the administration of the vaccination law should be transferred from the Poor law authorities to the hands of the sanitary authorities.

(c) As to the need for the establishment of thoroughly well-equipped laboratories for the preparation of a supply of glycerinated calf lymph adequate to meet all ordinary demands and for the systematic inspection of all establishments where lymph is prepared in this country

(d) As to securing a legal definition of what constitutes efficient vaccination and as to requiring all certificates of vaccination to state if the vaccination has been efficient or not

The league will assist all persons who have the opportunity to make known by means of leaflets lectures meetings, and the like the necessity for and the value of vaccination and revaccination This and other work will, of course cost money Members of the league promise at least 5*s* annually while associates give not less than 2*s*. 6*d* Cheques and postal orders may be sent to the secretary Dr. Edward J Edwardes at the offices of the league 53, Berners street London, W The bankers are Messrs. Robarts, Lubbock, and Co. 15, Lombard street, E.C We cordially welcome the league, for there is plenty of work for it as well as for the Jenner Society Only by steady work and constant pressure upon Parliament can the libels and misstatements of the baser sort of anti vaccinationist be overcome.

THE DISTRIBUTION OF PLAGUE

THE weekly return of the Director-General of the Sanitary Department of Egypt shows that for the week ending June 22nd there were 5 new cases of plague admitted all of them occurring in natives. The deaths numbered 2, the recoveries 14, and 13 cases remained under treatment. A telegram from the officer administering the Government of Hong Kong received at the Colonial Office on June 24th states that for the week ending June 21st there were 49 fresh cases of bubonic plague and 51 deaths.

THE KING'S TUESDAYS

THE principal events in the life of His Majesty, King Edward VII. have happened on a Tuesday—viz. on Tuesday Nov 9th, 1841, His Majesty was born on Tuesday Jan. 25th, 1842, he was baptised on Tuesday March 10th 1863, he was married on Tuesday Dec. 8th, 1863, he was appointed a member of the Privy Council on Tuesday Nov 21st, 1871, it was definitely ascertained that he had contracted typhoid fever, on Tuesday Feb. 27th 1872, he attended the Public Thanksgiving Service for his recovery on Tuesday Jan. 22nd 1901 he succeeded to the throne, on Tuesday Jan. 29th, 1901 the Royal Standard was hoisted at Marlborough House for the first time, and on Tuesday June 24th, 1902, His Majesty underwent an operation for perityphlitis As an exception to the above-mentioned cases it may be stated that it was on a Monday (July 18th 1898) that the King sustained a fracture of the left patella through missing his footing while descending the spiral staircase at Waddesdon Manor during a visit to the late Baron Ferdinand de Rothschild.

DISABILITIES OF THE POETIC TEMPERAMENT

IT has been said that every good physician is a poet,' and like most aphorisms, the saying combines a modicum of truth with a large leavening of mistaken notion. The idea that the author of this remark wished to convey was the perfectly correct one that something of the ready sympathy and something of the emotional susceptibility which belongs to the poet must be present in the character of any man who is to be highly successful in medically understanding and treating his fellow creatures. The practice of medicine, an art which deals with the minds and bodies of human beings let it be founded to however great an extent upon exact science, cannot be, and never will be, successfully pursued by the kind of man who is called hard." A hard rugged exterior is the familiar apparel of the medical practitioner of a certain class of novel. The writers of such books are careful, though to let it be seen that this forbidding appearance and this harsh manner conceal an unusual softness of heart, and in doing so they are not merely being just to the medical profession but they are acting in accordance with a recognised and correct opinion—to wit, that a doctor must be kind. So far then our claimant for poetic attributes in the physician is justified. There is however a great deal on the other side of the question that he overlooks That very sympathy which is the essence of the poetic temperament is a dangerous asset to the practitioner of medicine At least, if it is essential to the perfection of his character as a physician it must be kept sternly under control in a manner that would ruin its favourable influence upon a poetic output. With the poet everything that appeals to his sympathy everything that touches the strings of his heart, should move them to a musical note. When the poet feels he expresses his feeling and the expression is poetry He has been described as a man who expresses what other people only feel With the physician, on the other hand a prime duty is often not only not to express but even carefully to hide his real feeling When he realises the gravity or the hopelessness of a case is he to weep at the bedside? That would be the poetic attribute to the situation, it is scarcely that of the true medical man. In another way too the poetic temperament has disabilities tending to encumber the physician. The poet's qualities are in constant strife with reticence The physician, it has been well said, must have not only sense but reticence Confidence in the inviolability of confidences is an essential element of a patient's trust in his medical man. Stern must be the control which the poetic physician exercises over his natural tendencies, for reticence and the poetic temperament are natural foes The matter-of-fact man may lay this balm to his soul, that if he cannot be a great physician at least he is much more easily a harmless one than his fellow with the great possibilities—and great disabilities—that accompany the poetic temperament.

THE BOARD OF TRADE AND THE ELECTRICAL ENGINEERS

On June 18th a deputation from the Institute of Electrical Engineers was received by Mr Gerald Balfour, President of the Board of Trade The deputation, which included amongst its number Lord Kelvin and Sir Michael Foster, urged that something should be done to remove impediments which they stated stood in the way of the industrial development of electricity One of their chief grievances appeared to be the fact that local authorities possess the power to oppose, and do often actively oppose, electrical enterprises which they, rightly or wrongly, think would be disadvantageous to the people who live in the districts which they represent, and the further fact that Parliament frequently listens to the expression of opinion given by local bodies concerning local interests Mr Gerald Balfour pointed out that the number of vested interests existing in an old country is necessarily greater than that in a newly populated one and that for that reason the rapid developments possible in a sparsely populated area cannot take place in London. The President of the Board of Trade was unable to promise that there was any prospect of immediate legislation which would facilitate the extension of the industrial application of electricity A delay in this question is not altogether a matter for regret. At the present time the risk to life to which those engaged in the application of electricity to trade purposes are exposed has not received sufficient attention. A committee appointed by the Home Office recommended that a number of regulations should be made for the protection of those engaged in the work and the regulations advised were made chiefly on the opinion of Professor C V Boys and of other well known electricians Since the report of the committee was published experience has proved that exposure to a current of electricity is a source of greater danger than some professional electricians supposed Mr Hamilton P Smith, in his chapter on "Electric Generating Works," which forms part of the book edited by Dr Thomas Oliver on "Dangerous Trades,"[1] deals fully with this question and gives examples of cases in which fatal results have occurred from exposure to electric currents which, according to the previous teaching of electricians, should not have produced lethal results On the other hand, from several papers read before the Institution of Electrical Engineers on Feb 27th, 1902, it would appear according to their authors, that the dangers of electric shock are generally exaggerated One paper was published in our issue of March 8th, 1902, in which the author, Mr F B Aspinall, made some valuable suggestions as to treatment in case of shock. In a leading article in the same issue we pointed out that the question of the mode of death by electric shock was not fully settled, although there was much to support the view that the heart is the most susceptible of the vital organs and that death from electric shock is very often death from arrest of the heart's beat. Artificial respiration should therefore always be made use of Dr Oliver's recently published book has already been referred to in laudatory terms in the columns of The Lancet,[2] and the chapter on Electric Generating Works will be found a most instructive one, although it is somewhat full of technicalities At the present moment we are only concerned to point out that it is necessary in the public interest that the dangers of strong electric currents should be appreciated and that adequate precautions should be taken for the protection, not only of those engaged in the trade, but of all those who might suffer from the absence of sufficient protection from highly charged wires in the streets. It is due to the medical department of the Board of Trade to point out that the staff is thoroughly alive to the importance of the subject and it is satisfactory to note that Dr Arthur Whitelegge in his recently issued report[3] congratulates the Board on the appointment of an electrical inspector, Mr G S. Ram, M Inst. E E, whose term of office commenced on May 1st.

THE DINNER OF THE OBSTETRICIANS AND GYNÆCOLOGISTS OF THE EMPIRE

Sir James Graham, lecturer on midwifery at the University of Sydney, made some interesting remarks upon British obstetric medicine at the dinner of the Obstetricians and Gynæcologists of the Empire held on June 24th at the Hôtel Métropole, London The first passage in his speech which excited the admiration of the audience was a reference to the fact that the dinner had taken place at a time when the Angel of Peace had again visited our shores, smoothing the wrinkled front of war and turning the horrors of a stupendous campaign into a joyful season of delightful pleasure. He then proceeded to draw a comparison between the history of British obstetric medicine and the history of the British Empire. British obstetric medicine, he said, appeared first as a small speck on the map of British medicine but at the present time it stood out as a strong branch of the science of medicine It had attracted during its process of growth a large body of eminent men and of distinguished investigators who had been fired by the enthusiasm of scientific research. He declared that it was with a sense of just pride that he drew their attention to the fact that among the distinguished men who had adorned obstetric medicine the names of Simpson and Lister were acknowledged as the foremost by the whole world. Loud applause greeted the orator after this sentence and he gained still further plaudits by saying that those leaders of thought had made experiment possible. A large field of enterprise to the scientific worker had been opened up and it had brought British obstetric medicine to its present position of honour and esteem, decorated with garlands which many a joyous mother and living child had woven around it. Professional men who worked in distant parts of the empire found difficulty in adequately expressing what they owed to the teaching of the British obstetricians. Nothing made them feel their comparative national youth in the lands beyond the sea more than the fact that they had contributed so little to the common stock of obstetric medicine Not only did the dwellers in those far lands love the old country with passion but there had been transplanted into their midst, in addition to the old laws, customs, language, and religion, an intense love for the aspirations and ideals of those at home which they humbly and earnestly were seeking to follow The lives and examples of the famous men who had adorned British obstetric medicine were beacon lights on the professional path of those on the other side of the world, and those lives were rendered sacred by the memory of their character of their labours and of their genius. Their professional trials, their doubts and difficulties, their temptations, and their honours were all separate strands which woven together constituted the bond which kept them together Sir James Graham in concluding remarked Sir may it be our good fortune to maintain the high traditions of our calling and if possible, to add to its history and to hand down to those who follow even a better record than we ourselves have received." Dr (now Sir) J Halliday Croom (President of the British Gynæcological Society) who was one of those who responded to the toast proposed by Sir James Graham of British Obstetric Medicine ' prophesied that in the course of the next generation gynæcology would have become part of general surgery and gynæcologists would have become absorbed in the ranks of general surgeons. Mr Alban H. G Doran proposed 'The Guests and a speech by Dr F H Champneys giving the company the toast of 'The Chairman was followed by a reply from Sir John Williams in which he earnestly sought to interest the profession beyond the sea in the study of comparative human pathology He pointed out that the British Empire contained many different races and the study of comparative human pathology must be carried on at the present time because the tendency of races was to mix and to result in a type representing no definite characteristics Beyond that there was much work to do in the way of coördinating the work of gynæcologists and obstetricians

[3] Annual Report of the Chief Inspector of Factories and Workshops for the year 1901, Part I Reports 1902.

THE TURNING EFFECT OF A THUNDERSTORM ON FOODS SUSCEPTIBLE TO CHANGE

DURING serious electrical disturbances in the atmosphere it is well known that beer may become ' hard, milk may go sour and meat may frequently turn. Considerable speculation has arisen as to the cause of this change. It has been suggested that an ozonised state of the air due to electric discharge has something to do with it or that the formation of nitrous acid in the air is responsible for the change. It is, however not probable that the atmosphere undergoes any chemical change sufficient to account for the extent to which certain foods turn. Moreover any important quantity of ozone or nitrous acid would be calculated to exert a preservative effect, as both are powerful antiseptics It may be urged again that the phenomenon is due to oxidation by means of ozone, but this can hardly be the case in view of the large quantities of beer and milk that are soured in relation to the very small quantity of ozone which a thunderstorm produces. In the case of meat, at any rate the turning can scarcely be attributed to the action of ozone or of oxygen. The change is probably due not directly to chemical agencies but purely to a disturbance of the electric equilibrium. It is well known that an opposite electrical state is set up by induction, so that an electrical condition of the atmosphere induces a similar condition, though opposite in character in the objects on the earth. Persons near whom a flash of lightning passes frequently experience a severe shock by induction though no lightning touches them and in the celebrated experiment of Galvani he showed that a skinned frog in the neighbourhood of an electrical machine although dead exhibited convulsive movements every time that a spark was drawn from the conductor In the case of milk turning" or of beer hardening" or of meat becoming tainted it is probably therefore, an instance of chemical convulsion or it may be of a stimulus given to bacteriological agencies set up by an opposite electric condition induced by the disturbed electrical state of the atmosphere. Although these changes are most marked during a thunderstorm, yet undoubtedly they occur at other times, though not to the same degree when there is no apparent electric disturbance. But even when the sky is clear the atmosphere may exhibit considerable electrical tension. The electroscope constantly shows that a conducting point elevated in the air is taking up a positive charge (as a rule) of electricity the tension rising with the height of the point. This effect increases towards daybreak until it reaches a maximum some hours after sunrise. It then diminishes until it is weakest a few hours before sunset when again it rises and attains a second maximum value some hours after sunset, the second minimum occurring before daybreak. There are accordingly constant changes of electrical tension going on changes however which are more rapid and much more marked during a thunderstorm and which are quite powerful enough to exert an evil influence on certain articles of food or drink susceptible to change, notably meat, milk, and beer or cider There is no doubt that the unfavourable effects on the feeling of well being experienced by many individuals, such as headache and oppression and nervous distress on the advent of a thunderstorm have a similar foundation and are due to the same electrical differences of potential, the effects passing away as the disturbed condition of the atmosphere or the storm subsides.

THE EGYPTIAN MEDICAL CONGRESS

A YEAR ago it was decided to hold a congress of medicine in the buildings of the Government Medical School in Cairo during the third week of next December and we understand that the preliminary arrangements for its success are now fairly advanced. The Khedive and his Ministers have warmly accepted the scheme and will not be lacking in showing hospitality to visitors and in giving Government aid in various ways of which printing the proceedings is an important item. Already 300 medical practitioners resident in Egypt have joined the congress, and 250 from Europe and other parts have announced their intention of being present. Steamship companies will carry members of the congress at a reduced rate to Egypt, and once arrived there they will find special facilities while staying in the hotels and while making excursions in the country The coming winter in addition *to the usual attractions of Egypt*, will allow foreigners to see for the first time the finished dam at Assouan and the new Egyptological Museum with all its assorted treasures. In every European country some honorary presidents have been appointed those for Great Britain including Sir William Church Bart. K.C B. Sir Frederick Treves, Bart. K.C.V O C B Sir Christopher Nixon Sir W Taylor K.C B. Director General of the Army Medical Service Dr Patrick Manson, C M G and Professor A. E. Wright of Netley Delegates have already been appointed to represent various bodies, such as the Royal College of Physicians of London the Royal College of Surgeons of England the Royal College of Physicians of Ireland, the Clinical Society of London the Laryngological Society of London, the Royal Medical and Chirurgical Society the Rontgen Society and other societies The work of the congress is to be divided among only four sections Medicine, with Dr F M Sandwith a one of the vice-presidents Surgery with Mr H. M. N Milton as president and Mr F C Madden as a vice-president Ophthalmology with Dr E C. Fischer as vice president and Tropical Diseases presided over by Dr M A. Ruffer An English committee under the presidency of Sir Frederick Treves has been formed to forward the interests of the congress, and Sir Thomas Smith Bart. K C V O Dr Stephen Mackenzie, Sir Lauder Brunton Dr Savage, Sir Victor Horsley Dr James Taylor and Mr W Watson Cheyne C B most of whom have recently travelled in Egypt, have consented to act upon it. Dr W Page May, of 9, Manchester-square, London, W , has been appointed honorary secretary of this local committee, and to him all questions on the subject should be addressed In wishing success to the first Egyptian Congress of Medicine we may remind those of our readers who are fortunate enough to be able to take a winter holiday of the saying of an old Jewish physician "He who hath not seen Cairo hath not seen the world Her soil is good, her Nile is a marvel, her air is soft with an odour above aloes, refreshing the heart And how should Cairo be otherwise when she is the Mother of the World?"

THE PREVALENCE OF SMALL-POX

THE following figures show the number of patients admitted to the various hospitals of the Metropolitan Asylums Board for the dates mentioned —On Saturday, June 28th, there were 14 fresh cases , on Sunday, the 29th, there were eight fresh cases , on Monday, the 30th, there were 12 fresh cases , on Tuesday, July 1st, there were 14 fresh cases , and on Wednesday, the 2nd, there were six fresh cases. For the week ending June 28th 15 fresh cases of small pox were notified in the county of Essex, and owing to the marked diminution in the number of cases the weekly list hitherto issued by the medical officer of health will be discontinued for the present, its place being taken by a monthly return

OPTIC NEURITIS PRIMARILY PRODUCED BY SYPHILIS

OPTIC neuritis primarily resulting from syphilis is decidedly rare and, indeed, its existence has been denied by some writers In the majority of cases of optic neuritis following syphilis of some years' standing the neuritis has been observed to follow the formation of a cerebral gumma, but in the class of cases referred to below the antecedent condition was one of recent syphilis directly producing the symptoms in question Leber states that the optic neuritis of primary syphilis is different from that secondary to cerebral gumma, but the former disease is, as already stated, so rare that Horstmann (1889) was able to collect only eight cases from medical literature In the *American Journal of the Medical Sciences* for June Dr C A Veasey of Philadelphia reports two cases of the disease, together with the results of treatment The first case was that of a man, aged 45 years, who had been suffering from growing dimness of sight and diminution of visual acuity for a fortnight. The ocular media were clear and the pupillary reactions were normal Ophthalmoscopic examination showed a moderate degree of papillitis more marked in the left optic disc The patient had had a syphilitic chancre three months previously, the infection being followed by the development of a characteristic cutaneous rash and mucous patches The field of vision was symmetrically contracted but there was no central scotoma The patient had been taking mercury irregularly He was now treated with mercurial inunctions and rapidly increasing doses of potassium iodide. Improvement began in a week and in two months the optic neuritis had disappeared and vision was normal The second case was that of a woman, aged 43 years, the wife of the above patient. She suffered from gradually increasing inability to see objects Ophthalmoscopic examination showed commencing papillitis in the right eye and moderate papillitis in the left. The patient had been infected with syphilis by her husband and had been taking mercury irregularly since then The field of vision was contracted only in the left eye. She was put through the same treatment as her husband with the result that the papillitis subsided in six weeks and vision was restored to the normal soon after The very favourable results of treatment in these two cases are attributed by Dr Veasey to the early administration of mercury and iodides, as it has been proved that in cases of such neuritis occurring more than a year after infection recovery was rarely obtained.

THE WASTE OF WATER IN CITIES

PARIS was one of the cities which were held up as examples to London of the beneficial effects of a municipal water-supply and M Gaston Cadoux, chef de bureau of the Prefecture of the Seine, was good enough to come, at the request of the London County Council, that he might instruct Lord Llandaff's Commission[1] on the question. *Le Figaro* of June 28th, which is usually well informed on all matters Parisian, gives an amusing sketch of the effects of the heat on the chief director of the water supplies of the city He will not agree with his secretary that the climatic conditions are superb—in fact, he hates dry and hot weather He sees from the windows of his office a profusion of vegetables and of flowers The vegetables are washed in water and they will be cooked in water, the flowers will be put into water to keep them fresh. In a few days the water will fail and then they will blame him. It had been prophesied that there would be no heat and no drought before the end of June and he did not therefore expect to have to take any "special measures" before July The secretary inquires as to the nature of the special measures which will be adopted "What naturally would they be? We shall limit the consumption of water, we shall put the consumers on a fixed allowance, we shall close the conduits That is the best way of preventing the Parisians from being without water" If the *Figaro* is not too severe on the director of the Paris water supplies it must be admitted that his views as to the waste of water accord very accurately with those of some of the present metropolitan water company directors and of some of their engineers

A NEW GASOMETRIC METHOD FOR THE QUANTITATIVE DETERMINATION OF FREE HYDROCHLORIC ACID IN THE GASTRIC JUICE

A KNOWLEDGE of the amount of free hydrochloric acid present in the gastric juice is frequently an important element in diagnosis and many analytical processes have accordingly been devised for this purpose. The well known method of Sjoqvist depends on the fact that when gastric juice is evaporated with barium carbonate and the residue gently ignited the organic acids are destroyed, but the barium chloride produced by the action of the free hydrochloric acid remains unaffected and can be estimated as usual. This may obviously be done either by precipitation and weighing or volumetrically, but Professor E Riegler of Jassy, in Roumania, has suggested a gasometric process which he considers to be simpler than the preceding and more applicable for clinical purposes. His method, which is described in the *Deutsche Medicinische Wochenschrift*, of June 19th, is based on the reactions (1) that barium iodate is precipitated when a solution of barium chloride is treated with iodic acid, and (2) that nitrogen is evolved from a mixture of barium iodate and hydrazin sulphate. He mixes 10 cubic centimetres of gastric juice with half a gramme of barium carbonate in a platinum capsule thoroughly with a glass rod, evaporates to dryness in the water bath, and ignites gently till the ash becomes grey The residue is extracted with a small quantity of boiling water, which must not exceed 40 cubic centimetres, and this solution is treated in a small flask with five cubic centimetres of a 6 per cent. solution of crystallised iodic acid, shaken, and left at rest for a quarter of an hour The precipitated barium iodate is then washed on a filter until the total filtrate and washings measure 100 cubic centimetres, after which the filter with its contents is placed in the inner compartment of the evolution flask of a nitrogen apparatus—namely, either a Knop-Wagner azotometer or a Riegler's urea apparatus. 40 cubic centimetres of a 2 per cent. solution of hydrazin sulphate are placed in the outer compartment of the evolution flask, which is then immersed in a vessel of water at the temperature of the room After the lapse of 10 minutes the usual flexible air tight connexions are made between the flask and the graduated burette of the apparatus, and the flask is violently shaken for half a minute at short intervals until its contents, which at first were yellow from liberated iodine, become ultimately colourless. For each two molecules of hydrochloric acid six atoms of nitrogen are evolved. The volume of nitrogen after reduction to 0° C. and 760 millimetres pressure gives when measured in cubic centimetres and multiplied by the coefficient 1·083 the weight of the hydrochloric acid in milligrammes to which 3·2 milligrammes must be added for the amount of barium iodate dissolved in 100 cubic centimetres of filtrate and washwater If the foregoing analysis be performed without igniting the residue left on the water bath the result will give the total acidity of the gastric juice expressed as hydrochloric acid

---

THE CAMPAIGN AGAINST PALUDISM IN THE ROMAN CAMPAGNA

IN order to investigate the progress of the campaign against malaria which is being carried on in the Roman Campagna under the auspices of Professor Grassi Dr Guiart of Paris paid a visit to Ostia last September and has recorded his observations in a short article which appears in the *Archives de Parasitologie* vol. v No. 3. On the present occasion Professor Grassi determined to discard all mechanical means of protection against the attacks of the anopheles being desirous of testing the prophylactic virtues of quinine both alone and also in combination with other drugs. At first the peasantry residing in the vicinity refused to submit themselves to the treatment, but by degrees, on the appearance amongst them of malarial symptoms, they changed their minds and went voluntarily to the dispensary The preventive system recommended by Koch, in which quinine is given at intervals of eight or nine days having proved a failure the salt was administered daily but with equally bad results. Professor Grassi then made trial of a compound, containing quinine, iron, and arsenic which had been prepared for him by Signore Bisleri of Milan and found it perfectly successful This compound is employed in two forms—as a pill and in solution In the first form to which the name of esanophele" has been given the ingredients in each pill are as follows bichlorhydrate of quinine, 0·10 gramme citrate of iron 0·03 gramme, arsenious acid, 0·001 gramme, and bitter extract, 0·15 gramme. Adults take six pills daily for 15 days 90 pills in all. Children aged from seven to 14 years take four pills daily, from three to six years, two pills daily Under three years of age the medicament is administered as a solution which is said to possess an agreeable taste. This form, which is prepared in three strengths, has been named esanopheline." The foregoing is called the intensive" treatment the object being in the first place curative and secondly prophylactic After 15 days the daily dose for adults is reduced to two pills every morning while that for children and infants undergoes a proportionate reduction. It goes without saying continues Dr Guiart, that the treatment is very seriously supervised, the medicaments being given in the presence of Professor Grassi himself In a certain thrashing floor 120 workmen were employed of these 60 were left without treatment, and they all, without a single exception contracted malarial disease. The other 60 were given preventive ' esanophele " regularly and have remained healthy The Campagna around Ostia is being re-peopled, remarks Dr Guiart in conclusion. Instead of migrating as usual the inhabitants stand fast with their families and all keep in good health. No ague cakes are to be found the people all look well. Citizens from Rome now come to Ostia to spend their holidays. The anopheles continues to sting but no longer finds germs to disseminate

THE MEDICAL SERVICE OF INTERCESSION FOR THE KING

THE Guild of St. Luke organised on behalf of the medical profession a service of intercession for His Majesty the King at St Paul's Cathedral on the evening of July 2nd Although but short notice had been given upwards of 400 medical men were present, including Sir Dyce Duckworth, Dr Symes Thompson Mr George Cowell, and Mr Hutchinson. The music was directed by the Rev J B Croft of St. Matthew's Westminster The Litany was sung in procession and owing to the occasion being penitential the procession went by way of the north aisle. The clergy wore red copes and the Doctors of Medicine wore their scarlet. At the conclusion of the service, the order of which more or less followed the Office of Compline, the following message was sent to the Queen

The Guild of St. Luke, associated with many members of the medical profession, having assembled in St. Paul's Cathedral this evening to offer an intercessory service to Almighty God on behalf of His Majesty the King in his sickness, beg leave to present their humble duty to your Majesty and to express their fervent wishes for His Majesty's speedy and complete recovery

EMPYEMA OF THE FRONTAL SINUS IN MEASLES

EMPYEMA of one of the nasal sinuses is an exceedingly rare complication of measles At the meeting of the Société Médicale des Hôpitaux of Paris on May 30th M. Joseph Belin described a case in which empyema of the frontal sinus occurred A youth aged 18 years who had indifferent health was seen on Nov 12th, 1901 He had been ill three or four days and presented the early symptoms of measles—coryza and congestion of the palate and pillars of the fauces. Frequent douching of the eyes, mouth, nose, and ears with a saturated solution of boric acid was ordered In the afternoon the eruption appeared. On the following day the left eyelids were very œdematous the patient could not move them. *The œdema was not limited to the eyelids* Over the left frontal sinus there were redness and swelling and pressure was acutely painful. Inflammation of the frontal sinus was diagnosed and in addition to the boric douches previously ordered moist compresses to the left eye and instillations of menthol oil into the nose were prescribed. Next day the œdema was still greater and appeared to involve the tissues covering the right frontal sinus. On the following day the right side was no longer involved but there was severe pain in the position of the left upper lid and frontal sinus. Surgical intervention was intended bu epistaxis suddenly occurred from the left nostril and was soon followed by discharge of fœtid pus Improvement took place at once and the swelling of the forehead and left eyelids diminished. The purulent discharge continued for five or six days Swelling persisted only over the upper lid. Redness and fluctuation showed that there was an abscess in its outer part, which was incised. The pus discharged from the nose contained several varieties of microbes

—streptococci and staphylococci in great number, some pneumococci, and few micrococci tetrageni. The pus from the abscess contained streptococci and staphylococci aurei In empyemata of the nasal sinuses the pus rarely yields pure cultures but several microbes which are normally present in the naso-pharyngeal cavity

PRACTICAL POINTS FOR PLUMBERS

THE series of lectures for plumbers which has been commenced under the auspices of the Worshipful Company of Plumbers is an excellent departure. The first of these lectures was given at King's College, London, on June 20th by Mr E Russell, B Sc, F I C, the senior demonstrator of state medicine at the college, who chose for his subject "Physics and Chemistry in Relation to Plumbers' Work." The lecture was illustrated by diagrams and practical demonstrations In dealing with the action of water on metallic lead the lecturer pointed out the effect of very soft waters upon lead and of acid waters, while the protective action of lime salts which give water an alkaline reaction was demonstrated The part that gases play in this action was also discussed. The action, for instance, of beer highly charged with carbonic gas upon the lead of the beer-engine was quoted. It was stated that cabmen served with the first draught of beer in the morning get a large amount of dissolved lead but that after the first serving the beer runs quickly enough for practically no action to take place The lecturer also referred to other sources of the metallic contamination of water and in one instance he traced the perforations in a galvanised iron tank to a galvanic action which had been set up by the copper ball valve The lecture was given in the simplest terms and was listened to with evident interest, a short discussion following We wish the movement every success as a very practical step in education.

FLUORIDES IN BUTTER

DOUBTLESS the anticipation that the Preservatives Committee of the Local Government Board might be led to condemn the use of the most common preservative, borax, prompted certain butter-makers to look further afield for a preservative which so far would be beyond legislative control. For this purpose sodium fluoride appears to have been tried with some success According to Mr Otto Hehner, in a paper read at a recent meeting of the Society of Public Analysts the use of fluoride for this purpose is at present confined to certain French butters, but it is not unlikely especially in view of the fact that a small quantity of the fluorides suffices and that the determination of the actual amount is not easy, that the practice may spread Fluorides are not interdicted in any way in the recommendations of the Departmental Committee and it seems to us that before these recommendations are resolved into regulations under the Board of Trade the question of fluorides should be considered and determined. These salts have not been very fully studied in regard to their action on the organism but experiments have already established that they are inhibitory to the digestive processes even in the very small amounts used In view of this fact it would be very regrettable, we think, if the Departmental Committee did not take cognisance of this matter before allowing its recommendations to become part of the statutes regulating the sale of foods We cannot understand why the recommendations thus laid down have so far not been put into effect although the report was published over six months ago The delay, however, is perhaps fortunate in one respect, for it will enable the committee to deal with fluorides in the same way and in the same category as the better-known preservatives It is quite probable that the fluorides may not in the small quantity necessary for the purpose be any worse than borax, but it is desirable that the use of all antiseptics in food should be brought under effectual control.

PARALYSIS OF THE OCULAR FIBRES OF THE SYMPATHETIC NERVE IN PULMONARY TUBERCULOSIS

AT the meeting of the Société Médicale des Hôpitaux of Paris on May 23rd M A. Souques called attention to complication of pulmonary tuberculosis which appears not have been previously observed. He showed a man, the subjec of chronic pulmonary tuberculosis, who presented symptom of paralysis of the left cervical sympathetic nerve—myosis, narrowing of the palpebral fissure, and retraction of the eye. Nothing in the history or condition of the patient pointed to any of the usual causes of this paralysis—affections of nerve roots, pachymeningitis, myelitis, or bulbar lesions. M Souques was wondering whether there was any relation between the paralysis of the sympathetic nerve and the tuberculosis when he found in two other cases of pulmonary tuberculosis the same nerve symptoms. The pupil-dilating fibres of the sympathetic pass out from the spinal cord principally, if not entirely, by the ramus communicans of the first dorsal nerve, to the first thoracic ganglion of the sympathetic, thence they pass by the inferior cervical ganglion to the cervical sympathetic trunk. The first thoracic and inferior cervical ganglia are so nea one another that they are often confounded as one unde the name of the ganglion of Neubauer This ganglion is very close to the apex of the lung Hence inflammation of the latter may give rise to pleuritic thickening and adhesions which may involve and paralyse the pupil dilating fibres of the cervical sympathetic either in the rami communicantes or in the ganglion. In the absence of necropsies the exact position of the lesion cannot be stated

A BLEACHING POWDER EXPLOSION

SINCE bleaching powder is not a particularly stable compound it is not difficult to imagine conditions under which it would evolve gas and cause an explosion. Neverthele accidents of this sort do not appear to be of frequent occu rence, which may be attributed to the fact, perhaps, that bleaching powder is commonly sold to the public in a loose package When the powder is contained, however, in an air tight tin the gas evolved may accumulate in sufficient quantity to give rise to pressure This apparently was what happened in a case which was the subjec of an action in the King's Bench Division on June 30th The plaintiff stated that she purchased a tin of chlorinated lime at a branch establishment of the Army and Navy Coöperative Society The tin was provided with a lever top which on being eased was suddenly forced outwards and a portion of the contents of the tin went into her eyes and caused great pain Evidently something of the nature of an explosion had occurred, for the floor was covered with white powder within a radius of seven feet from the tin and the lid of the tin was found in the fireplace 10 feet away Eventually the jury awarded the plaintiff £175 damages and no doubt they were very much impressed by an experiment made on behalf o the defence A witness for the defence proceeded to ope a similar tin in court and as soon as the lid was eased a quantity of the contents was discharged and scattered itself on the witness's clothing Strong freshly prepared chlorinated lime does undoubtedly give off oxygen gas under certain circumstances We have known a mixture of chlorinated lime and bicarbonate of soda to explode violently The moral of this case would appear to be that fresh chlorinated lime should not be packed in absolutely air tight cases or else directions should be given to prick a hole, however tiny in the lid before attempting to remove it This would allow the escape of any gas that may have accumulated and then the lid could be removed without danger

THE CHOLERA IN ARABIA OUTBREAK IN THE YEMEN

THE British delegate to the Ottoman Board of Health writes to us as follows During the past few weeks cholera, which had completely disappeared from the Hedjaz with the end of the Mussalman pilgrimage has broken out in the more southernly Arabian province of the Yemen. Although information is at present lacking which would definitely prove that the infection has been carried to the latter by pilgrims returning from the Hedjaz, it is highly probable that the outbreak in the Yemen has been brought about in this way The outbreak was first reported by telegram from the quarantine station at Camaran on May 10th. One of the medical officers of the sanitary service was at once despatched to Sabia, the scene of the epidemic, to report upon the nature of the disease Sabia is stated to be an Arab town with about 22,000 inhabitants, living in *ariches* or mat huts. It is about seven hours journey from the Red Sea coast and is described as situated in a deep valley entirely devoid of vegetation. It is provided with a water supply of very bad quality and is said to be in the worst of sanitary conditions The population resisted all attempts at treatment or at isolation and other precautionary measures and the medical mission had to content itself with examining a few of the patients and determining the nature of the disease. The description of the symptoms contained in the reports received up to the present leaves practically no room for doubt that the disease is true Asiatic cholera. Down to May 20th the outbreak was confined to Sabia itself to the village of Omeh Hassim to the north and to two other villages named Selama and Melche. About 200 cases and 80 deaths were believed to have occurred in all down to the date just named This outbreak being confined to the interior of the country the measures taken to control it are in the hands of the Turkish Government, but, in accordance with precedent, the services of the medical and other employés of the sanitary administration (under the Ottoman Board of Health) have been lent to the Government. The measures have taken the nature of a cordon round the infected district and certain dispositions to prevent the disease spreading to the surrounding districts or to the coast. Later telegrams from Hodeida, on the Red Sea coast, have reported an extension of the disease to the district of Abon Arish, but telegrams from other sources have, on the other hand, denied the statement."

THE prizes will be distributed to the students of the medical school of St. Thomas's Hospital on July 10th at 3 P M, by Sir Henry F Norbury M D K.C.B. Director General of the Medical Department of the Royal Navy in the Governors Hall of the hospital before and after which the various departments of the hospital and school will be open for the inspection of visitors.

A GARDEN party will be held at the Epileptic Colony Chalfont St Peter Bucks, on July 9th, when visitors will be afforded an opportunity of seeing the colonists engaged in their usual work upon the farm, in the gardens in the workshops, and in the laundry

---

THE annual meeting of the Association for the Oral Instruction of the Deaf and Dumb will be held at the Portman Rooms (Dorset street entrance) on Wednesday July 9th, 1902, at 3 30 P M when a short illustration of the system will be given. The Earl of Crewe will preside.

THE STATISTICS OF CREMATION

BY SIR HENRY THOMPSON BART, F R C S. ENG

CONSULTING SURGEON TO UNIVERSITY COLLEGE HOSPITAL, ETC.
PRESIDENT OF THE CREMATION SOCIETY OF ENGLAND SINCE 1874

I AM indebted to my friend M Georges Salomon, secrétaire générale de la Société pour la Propagation de l'Incinération de Paris, for the following statistics of French and other European crematoria for the year 1901

The following facts are gathered from the report read and speeches made, by M Georges Salomon and Dr Bourneville at the annual meeting of the Société pour la Propagation de l Incinération de Paris.

Germany possesses seven crematoria. The following table gives the number of cremations performed at each during the year 1901 —

Gotha ..	218	Jena ...	85
Hamburg	181	Mannheim ..	23
Heidelberg	104		——
Offenbach	82	Total	693

The crematorium at Mannheim was opened in February 1901 while the seventh—at Eisenach—was only inaugurated in January last. The total shows a considerable increase on that of the previous year Recently a petition signed by over 3000 medical men has been presented in the Reichstag with a view of rendering compulsory the cremation of persons who have died from infectious diseases.

England also possesses seven crematoria. The following table gives the number of cremations at each for 1901 —

Woking	273	Hull	17
Manchester	95	Darlington	2
Liverpool	40		——
Glasgow	18	Total	445

Those at Hull and Darlington only commenced working during the course of the year while the seventh that at Leicester has not yet been inaugurated Yet another is in process of construction in the north of London on a tract of land several acres in extent and 2000 trees have already been planted there so as to form a park round the crematorium It is expected that it will be ready to commence operations before the end of the present year The total of 445 cremations for England for 1901 compares with 301 in 1900 and 240 in 1899

There are 26 crematoria in the United States of which 24 are in operation (see below)

In Canada, notwithstanding the opposition of the Roman Catholic clergy the legislature of Quebec has declared the legality of cremation and a crematorium has just been inaugurated at Montreal in which special regard has been had to the beauty of the building and its surroundings.

Returning to Europe we find that Italy possesses 22 crematoria, the last opened being at Pistoia, which was inaugurated during the meeting there of the fifth congress of the Italian cremation societies in October last. The only statistics furnished are those of Bologna, where 21 cremations were performed in 1901 (see below)

In Switzerland there are three crematoria—viz. at Zürich, Basle, and Geneva. At Zürich 127 cremations were performed as compared with 116 in 1900 In Geneva the first body was burned on March 8th last only A fourth crematorium is in course of erection at St. Gall which is expected to cost about £3000

Sweden possesses crematoria at Stockholm and Gothenburg and Denmark possesses one at Copenhagen, at which 34 cremations were performed in 1901 as against 28 in 1900

In Austria Hungary societies for the promotion of cremation continue to be formed under the influence of the Vienna society Die Flamme" and branches exist in Budapest, Innsbruck Gratz, Prague, and Mährisch-Ostrau but the practice of cremation has not yet been legalised.

This right however has been conferred on Madrid by a royal decree of August 3rd 1901, which bases its introduction on hygienic grounds.

Even in Russia, in spite of the protestations of the Procurator of the Holy Synod, the Government proposes to issue a decree in favour of making cremation optional.

Finally, in France, we have the statistics for the crematorium at Père la Chaise, Paris, which are presented in tabular form with those of previous years for comparison Omitting hospital remains, &c., which are cremated in Paris, from the original report, but not deemed necessary to be quoted here, the number of cremations among private families from the commencement in 1889 to 1901 inclusive is 2299 Those for the last-named year were 306, as compared with 297 in 1900

I am able to add to the above, having directly communicated by letter with each of the crematoria in the United States, the following statistics to the end of 1901 —

No	—	1901	Total from commencement
1	Fresh Pond N Y	654	4557
2	Buffalo, N Y	50	534
3	Troy, Earl C N Y	19	166
4	Swinburne Island N Y	3	114
5	Waterville N Y	1	39
6	St Louis Miss	141	1195
7	Philadelphia, Pa.	119	1037
8	San Francisco "Odd Fellows" Cal	666	2201
9	San Francisco "Cypress Lawn, Cal	91	723
10	Los Angeles Cal	65	552
11	Boston, Mass	171	—
12	Cincinnati Ohio	89	736
13	Chicago	182	877
14	Mount Auburn Cem , Mass	119	169
15	Pittsburg Pa	24	239
16	Baltimore.	20	200
17	Lancaster, Pa	2	101
18	Davenport, Iowa	29	162
19	Milwaukee.	45	223
20	Washington	33	149
21	Washington, "Le Moyne."	1	43
22	Pasadena, Cal	46	158
23	St. Paul, Minn	20	76
24	Fort Wayne Ind	5	18

For Italy, besides Bologna above mentioned, I can add the following, the first column also showing total to the end of 1901 —

—	1901	Total from commencement
Asti	2	30
Bologna	21	176
Lodi	2	52
Udine	2	49
Rome	69	941
Venice	7	50
Modena ..	2	29
Milan	103	1647
Cremona	1	124
Spezia	5	5
Turin	23	260
Florence ..	16	301
And also—		
Basle (Switzerland)	17	68

Finally, as on every preceding occasion of publishing annual statistics of crematoria, I append the total of the cremations at Woking, of which the first took place in 1885, with three in number for that year, the total amounting to 2097 at the end of 1901 —

Record of Cremations performed at Woking from Commencement of Operations[1]

Year	No	Year	No.
1885	3	1895	150
1886	10	1896	137
1887	13	1897	173
1888	28	1898	240
1889	46	1899	240
1890	64	1900	301
1891	99	1901	273
1892	104		—
1893	101	Total	2097
1894	125		

THE GENERAL MEDICAL COUNCIL MR GEORGE JACKSON'S REPORT TO THE ELECTORS

MR. GEORGE JACKSON of Plymouth has sent us the following with a request for its publication —

In accordance with my promise to the electors I write a short *résumé* of the proceedings of the General Medical Council, touching especially on the points of general interest and those in which I took some small part The special meeting of the Council which took place in February was held for the special object of dealing with the question at issue with the Colleges of Physicians and Surgeons—viz , as to the recognition of certain schools as proper places for the commencement of medical studies. This question was referred to the May meeting to receive a report of the primary examinations As this has not yet been done no report was before the Council. It is, however, probable that some additional places, such as technical schools, may be recognised It is important that whilst no places be recognised which are unfitted as places of study, yet it should be made possible that the commencement of medical studies may be made at such places

The work of the General Medical Council is much more complex and varied than would appear to be the case to an outside observer

Judicial Duties of the Council

This session the work with regard to penal cases, which were to a great extent dealt with *in camera*, was very heavy and, I think I may say, somewhat painful. The Council was called upon to decide cases in which the moral character of medical men was brought into question, it being alleged against them that they had taken advantage of their positions as medical men to act improperly towards female patients These cases appeared to reveal a tendency on the part of the public to try to punish delinquents of this sort by means of the Council instead of by the ordinary courts of law It was, however, held by the legal advisers of the Council that the Council would be only doing its duty in dealing with such cases One satisfactory feature was the case of Dr Rendall who had been acting for the National Medical Aid Company He announced that he had discontinued his connexion with the company in obedience with the request of the Council. This will therefore have the effect of checking the advertising and touting for members by these medical aid societies.

The Financial Position.

One of the most important subjects brought before the Council on this occasion was the financial position of the Council. It is evident that unless some radical steps are taken the Council must become bankrupt. Its expenditure exceeds its income very considerably—last year by £1509 Various propositions, as it will be seen by the report, were made I moved a resolution to the effect that a small annual licensing fee of 10s. should be paid by all those medical practitioners who were in practice, not of course to apply to those who had already paid the £5 registration fee, for the first five years. The effect would be to bring the profession more in touch with the Council and possibly as one of the members suggested, lead to an increase in the number of Direct Representatives by the fact that representation should accompany taxation. Roughly speaking this plan should provide an income of £12,000 per annum. This would not be too much in the face of the additional work put on and expected of the Council. Some economies might also be practised—i.e. as suggested by Mr. George Brown, the grouping together of some of the corporations and so diminishing the number of Representatives instead of as at present, increasing it every time a new university is created or when the right to a Representative on the Council is also granted. I am glad to say that this proposition was supported by the three Direct Representatives for England and Wales

---

[1] From the Transactions of the Cremation Society of England, No XV published in the spring of 1902

The Midwives Bill

The report of the committee on this question was not accepted, it being thought that the Council had already done all that could be done but Mr Brown s resolution condemning the Bill, which I had the pleasure of seconding was passed by a large majority A matter of considerable interest to members of the medical profession was also carefully considered—viz. the regulations as to the necessary curriculum for the Diploma of Public Health, three months being substituted for six months as the period allotted for outdoor sanitary work and three months to be spent in attending a course of lectures on sanitary law and cognate subjects The conclusion that attention should be paid to methods of administration in an infectious hospital was adhered to. This is doubtless a very essential point, as in the provinces, at all events, medical officers of health have infectious diseases hospitals under their control.

The question of preliminary education was the subject of a deputation from the British Medical Association to the Education Committee of the Council, urging amongst other matters the institution of a preliminary examination by the Council itself. If this was done it would insure a uniform standard of efficiency and need not prevent universities, &c. holding their own examinations as well. The reply of the committee will be made in due course

Looking Back.

FROM

THE LANCET, *SATURDAY, JULY 3*, 1824

Taliacotian Operation for a New Nose. From the Gazette de Sante June 15

One of the most horrible deformities is undoubtedly that which results from the loss of the nose, and that operation may be regarded as a great triumph of surgery by which we are enabled to make if not a perfect, at least a supportable nose by taking a portion of skin sufficient for this purpose from the forehead of the patient. This operation, which has recently been called the *rhinoplastic* has been successfully performed by Professor DELPECH The patient who was the subject of it had lost his nose from the effects of syphilitic ulcers, after a long course of treatment, the operation was performed on the 4th of June 1823. In the month of August following the cicatrix was perfect, and the patient returned to Toulon his country where he became an object of general astonishment so happily was nature imitated by his artificial nose.

We learn from an English Medical Journal that Mr Travers a Surgeon of St. Thomas s Hospital recently performed the same operation but not with the same success half of the skin detached from the patient s forehead having mortified

QUACKERY *alias* SWINDLING

A fellow of the name of *Munstcall* who for some time past has been flourishing not a hundred miles from Liverpool, in the character of a Medical Practitioner and as a Member of the Royal College of Surgeons in London, has lately deemed it prudent to remove to this Metropolis and has taken up his residence in the neighbourhood of Cavendish square We consider it our duty to caution all persons against having any transactions with this worthless impostor He has duped and ruined hundreds in the North, and we suspect that it is his intention to be guilty of similar atrocities here. We however will frustrate his intention by exposing to the whole world the real character of the nefarious scoundrel and in doing which, though we shall execute a most irksome task yet we are confident it will prove of great public service.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8383 births and 4258 *deaths were registered during the week ending June 21st.* The annual rate of mortality in these towns, which had been 16 5 16 0, and 15 0 per 1000 in the three preceding weeks, further declined to 14 9 per 1000 in that week. In London the death rate was 14 4 per 1000 while it averaged 15 2 in the 75 other large towns. The lowest death rates in these towns were 4 1 in Hornsey 7 0 in East Ham, 7 6 in Bournemouth 7 7 in King s Norton 8 2 in Walthamstow 8 3 in Hanley 9 1 in Yarmouth and 9 3 in Wolverhampton and in Aston Manor the highest rates were 20 1 in Middlesbrough 20 5 in Barrow in Furness 21 0 in Tynemouth 21 8 in Rhondda 22 9 in Sunderland, 23 6 in Rochdale, and 24 6 in Wigan. The 4258 deaths in these towns in the same week included 481 which were referred to the principal infectious diseases, against 555 and 496 in the two preceding weeks of these 481 deaths 156 resulted from measles 103 from whooping-cough 60 from diarrhœa, 53 from diphtheria, 52 from scarlet fever 31 from small pox, and 26 from fever" (principally enteric) In Croydon Hornsey East Ham Reading Aston Manor Stockport and seven other smaller towns no death from any of these diseases was registered , while they caused the highest death rates in Tottenham West Bromwich St. Helens Rochdale, Barrow in Furness, Gateshead and Rhondda. The greatest proportional mortality from measles occurred in Burton-on-Trent West Bromwich, Rochdale Barrow in Furness, Sunderland Gateshead and Rhondda from scarlet fever in St. Helens from whooping-cough in Southampton and South Shields and from fever" in Burnley The mortality from diphtheria showed no marked excess in any of the large towns Of the fatal cases of small pox registered in the week 24 belonged to London four to West Ham and one each to Willesden West Ham and Liverpool but not one to any other of the 76 large towns. The number of small pox patients under treatment in the Metropolitan Asylums hospitals, which had been 1274, 1162, and 1035 at the end of the three preceding weeks had further declined to 861 at the end of the week 107 new cases were admitted during the week against 251 188, and 157 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday June 21st was 2450 against numbers increasing from 2207 to 2347 on the five preceding Saturdays 378 new cases were admitted during the week, against 319 310 and 282 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 261 200 and 166 in the three preceding weeks rose again in the week to 173, but were 15 below the corrected average number The causes of 51, or 1 2 per cent of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham Bristol, Salford Leeds Newcastle and in 47 other smaller towns The largest proportions of uncertified deaths were registered in Reading Birmingham Leicester and Liverpool

During the week ending June 28th 6823 births and 4293 deaths were registered in 76 of the largest English towns The annual rate of mortality in these towns which had been 16 0 15 0 and 14 9 per 1000 in the three preceding weeks, rose again last week to 15 1 per 1000. In London the death rate was 14 2 per 1000 while it averaged 15 4 per 1000 in the 75 other large towns. The lowest death rates in these towns were 6 5 in Wallasey 7 6 in Bournemouth 7 7 in Ipswich, 8 9 in Grimsby 9 0 in Hornsey 9 2 in Smethwick and in York and 9 5 in Croydon the highest rates were 18 8 in Manchester and in Barrow in Furness 19 9 in Warrington 20 0 in St. Helens 21 4 in Merthyr Tydfil, 21 9 in Liverpool, 24 2 in Oldham and 30 5 in Wigan The 4293 deaths in these towns last week included 476 which were referred to the principal infectious diseases, against 555 496, and 481 in the three preceding weeks of these 476 deaths 127 resulted from measles 117 from whooping cough, 59 from scarlet fever, 59 from diarrhœa, 54 from diphtheria, 34 from "fever" (principally enteric), and 26 from small pox. No death from any of these diseases was registered last week in Croydon, Walthamstow, Hastings, Northampton, Great Yarmouth, Grimsby, Bury, Rotherham, or York, while they caused the highest death rates in East Ham, Hanley, Coventry, Derby, St. Helens, Wigan, Barrow in Furness, Middlesbrough, and Rhondda. The greatest proportional mortality from measles occurred in Bournemouth, Plymouth, Derby, Barrow in Furness, Bradford, and Rhondda, from scarlet fever in Burnley, from diphtheria in Coventry and St. Helens, from whooping cough in Leyton, Norwich, St. Helens, from Barrow in Furness, Middlesbrough, and West Hartlepool, from "fever" in St Helens, and from diarrhœa in Willesden and Hanley The fatal cases of small pox registered last week included 17 which belonged to London, four to West Ham, two to Tottenham, two to Swansea, and one to Bootle The number of small pox patients under treatment in the Metropolitan Asylums hospitals, which had been 1162, 1035, and 861 at the end of the three preceding weeks, had further declined to 837 at the end of last week, 129 new cases were admitted during the week, against 188 157, and 107 in the three preceding weeks The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday, June 28th, was 2496, against numbers increasing from 2207 to 2450 on the six preceding Saturdays, 276 new cases were admitted during the week, against 310, 282, and 378 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 200, 166, and 173 in the three preceding weeks, further rose last week to 194, and were 21 above the corrected average. The causes of 35, or 0 8 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Bristol, Birmingham, Manchester, Salford, Newcastle, and 51 other smaller towns, the largest proportions of uncertified deaths were registered in West Ham, Liverpool, Warrington, and Blackburn.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 19 3 and 19 0 per 1000 in the two preceding weeks, further declined to 16 4 per 1000 during the week ending June 21st, but showed an excess of 1 5 per 1000 over the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 12 6 in Leith and 13 5 in Dundee, to 18 1 in Glasgow and 19 2 in Paisley The 531 deaths in these towns included 18 which were referred to measles, 17 to diarrhœa, 13 to whooping cough, four to scarlet fever, two to diphtheria, and not one to either small pox or "fever" In all 54 deaths resulted from these principal zymotic diseases in the week, against 57, 61, and 68 in the three preceding weeks. These 54 deaths were equal to an annual rate of 1 7 per 1000, which was also the death rate in the week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 13, 22, and 18 in the three preceding weeks, were again 18 in the week, and included seven in Glasgow, four in Edinburgh, four in Paisley, and two in Perth The deaths from diarrhœa, which had been 15, 16, and 18 in the three preceding weeks, declined again to 17, of which 13 were registered in Glasgow The fatal cases of whooping-cough, which had been 15 and 21 in the two preceding weeks, declined again to 13, and included four in Glasgow, three in Edinburgh, two in Aberdeen two in Paisley, and two in Perth. The four deaths from scarlet fever corresponded with the number in the preceding week, while the fatal cases of diphtheria showed a slight decline from recent weekly numbers. The deaths referred to diseases of the respiratory organs in these towns, which had been 116 and 129 in the two preceding weeks, declined again to 96, but were slightly above the number in the corresponding period of last year The causes of 26 or nearly 5 per cent., of the deaths registered in these eight towns were not certified

The annual rate of mortality in the eight Scotch towns, which had been 19 3, 19 0 and 16 4 per 1000 in the three preceding weeks, rose again to 19 2 per 1000 during the week ending June 28th, and showed an excess of 4 1 per 1000 over the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 15 9 in Leith and 17 8 in Aberdeen to 25 8 in Greenock and 29 7 in Perth. The 620 deaths in these towns included 16 which resulted from diarrhœa, 15 from measles, 14 from whooping-cough, four from scarlet fever, four from diphtheria, and four from "fever" In all 57 deaths resulted from these principal infectious diseases last week, against 68 and 54 in the two preceding weeks. These 87 deaths were equal to an annual rate of 1 8 per 1000, which was slightly above the mean rate last week from the same diseases in the 76 large English towns The fatal cases of diarrhœa, which had been 13 and 17 in the two preceding weeks, further declined last week to 16, of which seven occurred in Glasgow, four in Edinburgh, and four in Aberdeen The deaths from measles, which had been 18 in each of the two preceding weeks, decreased to 15 last week, and included six in Edinburgh, three in Glasgow, three in Paisley, and two in Dundee, The fatal cases of whooping cough, which had been 21 and 13 in the two preceding weeks, rose again last week to 14, of which four were registered in Edinburgh, three in Glasgow, two in Aberdeen, two in Paisley, and two in Perth. The deaths from scarlet fever, which had been four in each of the two preceding weeks, were again four last week, and all occurred in Glasgow The four fatal cases of diphtheria were slightly in excess of the numbers recorded in recent weeks, and included two in Edinburgh where two of the four deaths from "fever" also occurred. The deaths referred to diseases of the respiratory organs in these towns, which had been 129 and 96 in the two preceding weeks, rose again last week to 101 and were slightly in excess of the number in the corresponding period of last year The causes of 24 or nearly 4 per cent, of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 22 3, 19 8, and 19 7 per 1000 in the three preceding weeks, further declined to 17 9 per 1000 during the week ending June 21st. During the previous four weeks the death-rate had averaged 19 9 per 1000, the rates during the same period being 15 0 in London and 17 5 in Edinburgh The 130 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 13 from the number in the preceding week and included eight which were referred to the principal zymotic diseases, against eight, six, and 10 in the three preceding weeks, of these, five resulted from measles, one each from scarlet fever, from diphtheria, and from "fever," and not one from either small pox, whooping cough, or diarrhœa. These eight deaths were equal to an annual rate of 1 1 per 1000, the death rates from the same causes in the week being 1 8 in London and 1 5 in Edinburgh. The fatal cases of measles, which had been two, three, and four in the three preceding weeks, further rose in the week to five, while the mortality from diphtheria and that from "fever" corresponded in each case with that recorded in the preceding week. The 130 deaths in Dublin in the week included 25 of children under one year of age and 33 of persons aged upwards of 60 years, the deaths of infants showed a slight decline, while those of elderly persons were in excess of the number recorded in the preceding week. Four inquest cases and two deaths from violence were registered, and 51, or nearly two-fifths, of the deaths occurred in public institutions. The causes of four, or more than 3 per cent., of the deaths registered in Dublin were not certified.

The death rate in Dublin, which had declined from 22 3 to 17 9 per 1000 in the four preceding weeks, rose again to 19 9 per 1000 during the week ending June 28th. During the 13 weeks of the quarter ending on that date the death rate averaged 22 7 per 1000, the rates during the same period being 16 1 in London and 18 3 in Edinburgh The 145 deaths of persons belonging to Dublin registered during the week under notice were 15 in excess of the number in the preceding week, and included nine which were referred to the principal infectious diseases, against six, 10 and eight in the three preceding weeks, of these, four resulted from "fever," three from measles, two from scarlet fever, and not one from either small pox, diphtheria, whooping cough, or diarrhœa These nine deaths were equal to an annual rate of 1 2 per 1000, the death rate last week from the same diseases being 1 6 in London and 2 9 in Edinburgh. The fatal cases of "fever," which had been one in each of the two preceding weeks, increased last week to four, while the deaths from measles decreased from five in the preceding week to three last week. The 145 deaths in Dublin included 29 of children under one year of age and 30 of persons aged upwards of 60 years the deaths of infants slightly exceeded the number in the preceding week while those of elderly persons showed a decline. Three inquest cases and four deaths from violence were registered and 53, or more than a third of the deaths occurred in public institutions. The causes of 11, or more than 7 per cent of the deaths registered in Dublin last week were not certified.

THE SERVICES

THE CORONATION HONOURS

To be Knight Commander of St Michael and St George

Surgeon General H. H. Pinching Head of the Sanitary Department at Cairo

To be Knights Commanders of the Bath.

Inspector General of Hospitals and Fleets John Denis Macdonald R.N (retired)

Surgeon General John Andrew Woolfryes, C B., C M G honorary physician to the King

Surgeon-General Annesley Charles Castriot de Renzy C B. I.M.S (retired)

Surgeon General (ranking as Lieutenant-General) William Taylor C B., honorary physician to the King

To be Companions of the Bath.

Lieutenant-Colonel Patrick Fenelon O Connor I M.S

Fleet-Surgeon James Porter R.N

Inspector-General of Hospitals and Fleets Duncan Hilston R.N (retired)

Inspector General of Hospitals and Fleets, Robert Grant, R N

Lieutenant-Colonel Sir James Richardson Andrew Clark, Bart. (Brevet Major) R.A.M.C (Medical Staff Corps) (Militia)

Lieutenant-Colonel George Thomas Beatson (Medical Staff Corps) the Glasgow Companies, R A.M.C (Volunteers)

To be Companion of the Indian Empire

Lieutenant-Colonel T E. L. Bate, I.M S.

South African List

The King has also been graciously pleased to give orders for the following appointments to the undermentioned officers and soldiers in recognition of their services during the operations in South Africa.

To be Companions of the Bath.

Colonel J D Edge R A.M C

Lieutenant-Colonel W A. May R.A.M.C.

Lieutenant-Colonel R. V Kelly New South Wales Medical Corps.

Veterinary Lieutenant-Colonel T Flintoff, Army Veterinary Department.

Lieutenant-Colonel Henry James McLaughlin, Reserve of Officers (late R. A. M C.)

Lieutenant-Colonel C. E. Nichol R.A.M C

Major H. N Thompson, R.A.M C

Major W H. W Elliot, I M S.

Captain G Leslie, Medical Officer

To have the Honorary Rank of Captain.

Quartermaster and Hon. Lieutenant J B. Short, R A.M C.

Quartermaster and Hon. Lieutenant A. Freshwater R A.M.C. (since deceased).

To be Companion of St. Michael and St George

Mr A. L. Langman, jun. Langman s Hospital.

To have the Decoration of the Royal Red Cross

Superintendent Miss F M Chadwick Army Nursing Service (with hospital ship *Maine*).

Nursing Sister Miss M. C. S Knox, Army Nursing Service.

Nursing Sister Miss Elizabeth Cochrane Shannon Army Nursing Service Reserve, with Scottish National Hospital.

Miss H. Hogarth Army Nursing Service Reserve, hospital ship *Princess of Wales*

Mrs. George Cornwallis West, hospital ship *Maine*

Mrs. Theodosia Bagot, Portland Hospital.

Mrs T C. Wolley Dod, Mrs Keith, and Miss Knight, care of prisoners of war Pretoria.

Miss Frances Amelia Lowrie, Matron, Bourke Hospital Pretoria

Mrs. P H. Johnston, President Army Hospital Aid Society Natal.

Miss Ada Whiteman Maritzburg and Leper Hospital, Pretoria.

Miss Lucy Alice Yeatman Colonial Nurse, Ladysmith.

Mrs Melina Rorke, Colonial Nurse Bulawayo

Mrs. Redpath, Colonial Nurse, Ladysmith.

Mrs. Jessie Burrill and Mrs. Emma Francis Durban Women s Patriotic League.

Mrs. Jane Waterston and Mrs. Sclater Good Hope Society Natal.

Georgina, Dowager Countess of Dudley

Miss Ethel McCaul.

Mrs Kilpin and Mrs. Ball Good Hope Society

To be enrolled as Honorary Associates of the Grand Priory of the Order of the Hospital of St John of Jerusalem

Miss Martha Thomson Miss Sarah Emily Webb Miss Sarah Elizabeth Oram Superintendents and Miss Louisa Watson Tulloh Nursing Sister Army Nursing Service.

The notification regarding the above four ladies which appeared in the *London Gazette* of Sept. 27th 1901, is hereby cancelled.

To be enrolled as an Honorary Associate of the Grand Priory of the Order of the Hospital of St. John of Jerusalem —Miss Mary Cecil Florence Kate Cole Superintendent, Army Nursing Service.

The King has also been graciously pleased to give directions for the following appointments in recognition of services in this country the Mediterranean, and the Channel Islands during the operations in South Africa.

To be Companions of St Michael and St George

Lieutenant-Colonel Henry Charlesworth R A M C

Major William Grant Macpherson, R A.M.C

Kaisar i Hind Medal for Public Service in India

Captain T W A. Fullerton, I.M.S and Lieutenant Colonel J L. Poynder I.M S have been granted the gold medal.

Royal Navy Medical Service.

Deputy Inspector General (retired) J Lyon to be Surgeon and Agent at Manchester Staff Surgeons A M. Page to the *Hood* and J Parry to the *Australia* Surgeons H. C Arathoon to Haslar Hospital and H. W M. Rees to the *Vivid*

Royal Army Medical Corps.

Surgeon-General G J H. Evatt, A.M.S. Principal Medical Officer Western District, has been appointed Principal Medical Officer 2nd Army Corps, but will continue for the present to hold his position in the Western District in addition to his other duties.

Army Medical Reserve of Officers.

Surgeon Lieutenant Neish Park Watt, Forth Division Submarine Miners Royal Engineers (Volunteers) to be Surgeon Lieutenant.

Volunteer Corps.

Rifle 2nd Volunteer Battalion the Durham Light Infantry Surgeon Lieutenant G Stephen to be Surgeon Captain.

Volunteer Infantry Brigade Bearer Company

East Surrey Surgeon Major J J de Z. Marshall from the 3rd Volunteer Battalion the East Surrey Regiment, to be Surgeon Major and to command under paragraph 55A Volunteer Regulations.

South African Notes.

Civil Surgeons Francis Alban, and Boyd are on passage home from South Africa.

Civil Surgeon Clarke is progressing favourably

The Titles of Volunteer Medical Officers.

In a letter from the War Office dated June 25th, 1902, in answer to a communication from the Volunteer Medical Association, it is stated that Mr Brodrick notes that it is the opinion of the council of the Volunteer Medical Association that there is no inclination among senior medical officers of volunteer infantry brigades to drop the word brigade in the title brigade-surgeon lieutenant-colonel With reference to the recommendation of the council that the rank of colonel (or surgeon-colonel) may be granted after 24 years and recognition, I am compelled to say that in the particular instances he cites (ship and hospital practice) his arguments are somewhat puerile. Ships' surgeons are derived mainly from two classes firstly, young men freshly qualified who, perhaps, are somewhat run down from hard reading and who in any case seize the opportunity of their irresponsible position to see the world at the expense of some shipping company, and, secondly, practitioners of some years' standing who, owing to ill health, are obliged temporarily to give up their work on shore and who go to sea to recuperate The majority of sea-going surgeons remain in the same company for a few voyages only Surely they cannot expect to receive £300 or even £200 a year where there is no fixity of tenure on their side And even if the first-named salary were offered, what surgeon worthy of the title would be content to laze away his life on board ship where the opportunities of following up his profession are so few and the limitations to its practice so many? Your correspondent delicately remarks that many ships' surgeons are "scabs" The query is obvious

Most companies offer £10 a month to their prospective surgeons. At first sight the remuneration does not appear peculiarly generous, but consider the accompanying advantages—a free passage to some of the most interesting parts of the globe, social intercourse with people of all classes, nations, and opinions, a cuisine rivalling that of a first-class hotel, an assured social position (if the individual can maintain it), and, lastly—if one can call it an advantage—very little to do Furthermore, few men leave the mercantile service without having supplemented their income with private fees which they are allowed to receive but not to *demand* I need not refer to the question of hospital surgeons, the same law of compensating advantages applies

I am, Sirs, yours faithfully,
F B RYAN, M B R U I,
Late Royal Mail Service

June 29th, 1902.

A NEW METHOD OF KEEPING IN APPOSITION THE EDGES OF SURGICAL INCISIONS AND WOUNDS IN ORDER TO PROMOTE UNION

To the Editors of THE LANCET

SIRS,—In THE LANCET of June 28th, p 1839, is described a new method of keeping in apposition the edges of surgical incisions and wounds in order to promote union The idea is not new, any more than the inventive plagiarism, unconscious or otherwise If you will look back to your own esteemed pages of Sept 27th, 1884, you will see that Messrs Arnold and Sons made a similar suture for me, you will see that mine is a step further towards perfection, as a matter of fact, necessarily an evolution of that now described, which latter I found painful and inefficient and requiring, indeed, considerable energy to introduce, as must be so with sewing-needle points and arms of equal length Who are the "surgeons of highest rank" who recommend this suture? There are other very valuable modes of closing wounds not used for some reason or other The following is one I often used Take one or more couple or couples of curved surgical needles, thread them in couples Introduce *along* each side of the wound, bring the points to the necessary extent together (to close the wound), fix them by a piece of cork or indiarubber, bring the eye ends together to an equal extent, and tie the thread.

I am, Sirs, yours faithfully,
JAMES MACMUNN

Finsbury Pavement E C June 29th 1902.

MOTOR CARS FOR MEDICAL MEN

To the Editors of THE LANCET

SIRS,—Frequent inquiries have been made through your journal for information respecting a trustworthy and simple car and price within reach of the general practitioner I am running a car now which meets these requirements The car is built by the Pick Motor Co, Limited, Stamford, is of British workmanship throughout, and can be seen built in every stage at the works My car is a 6 h.p voiturette, double cylinder, two speeds, belt driven (Dicks), which are inclosed in case and protected from wet and dirt, when the bonnet is off the whole engine is *in situ* and the parts are easily got at, and the mechanism is so simple that anyone with ordinary knowledge can put it right. Another advantage is that you can easily get duplicates of any of the parts, as this is a standard type of car for which there is a demand One coil with a trembler is only necessary fo the two cylinders I can get up to 32 miles per hour spee and most hills can be climbed on the fast speed, in fact, I have had to use the low speed very little. Having seen a large number of cars of different types I do not know of one that can touch it for workmanship and reliability The price of my car complete is £150

Any tyre can be put on. I know none equal to the Goodrich single tube.

I am, Sirs, yours faithfully,
H. T BENSON, J P, L R C P Lond, &c.,
Member of the Lincolnshire Automobile Club

Market Deeping June 21st, 1902.

THE RECONSTITUTION OF THE BRITIS MEDICAL ASSOCIATION

To the Editors of THE LANCET

SIRS,—I shall be glad if you will kindly allow me to intimate to your readers that there will be a meeting of those members of the Association interested in the report on Tuesday night, July 8th, at 8 30, in the St. Martin's Town Hall, London —I am, Sirs, yours faithfully,

JAS BRASSEY BRIERLEY

ADMINISTRATION OF CHLOROFORM FROM A CLOVER INHALER

To the Editors of THE LANCET

SIRS,—In THE LANCET of June 21st, p 1779, Mr F Victor Millward, in describing his ingenious combination of two Clover inhalers, states that he considers it possible to administer chloroform alone from the inhaler after removal of the bag, but has not made trial of this method. That this is quite feasible I pointed out in a letter to your columns of Feb 9th, 1901, p 434 Since that date I have almost invariably administered chloroform from a Clover inhaler, minus the bag, of either the ordinary or large bore type and I find this method a great improvement on the frequent bottle tilting or ball squeezing inseparable from the open and Junker methods and as safe a method as is possible when chloroform is the anæsthetic. The large bore, although of service in administering ether, gives no additional advantage when the anæsthetic is chloroform, for which the ordinary bore is ample.

I am, Sirs, yours faithfully,
C HAMILTON WHITEFORD

Plymouth, June 21st 1901

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT)

Instructions concerning Electric Wire Accidents —The Natives of Ind Plague Epidemic and the Famine —The Value of Indian Opium. and Cigarette Smoking —1.

IN consequence of accidents from electric wires in Calcutta I understand that a committee consisting of ambulance lecturers and electrical engineers has been formed and that it has drawn up the following simple instructions for the police and the public.

ACCIDENTS WITH ELECTRIC WIRES

Notice —The thick trolley wires over the tramway lines and the electric light wires are the dangerous wires The other wires in the street are harmless so long as they do not touch the above wires but if they be broken and fall on and touch the above wires they then also become dangerous

Instructions —If a wire falls harmlessly leave it alone but prevent anyone from touching it. If the end hangs loose or the wire is an obstruction it may be pulled on one side by means of a stick or piece of rope and may be tied by means of string or rope out of the way b it must on no account be touched with the bare hands If it b necessary to use the hands they must be covered with a very thick dr cloth In moving a wire great care must be taken that it does not touch any other wire Never stand on a fallen wire. The constable must not leave his post until the wires have been made safe. If a wire falls on a person and winds round him or becomes entangled in the clothing the wire should be pulled away with a stick or by wrapping the hands in a thick dry cloth Great care must be taken that the wire does not touch the bare skin of the person or that of the rescuer

Injuries —A person injured by a fallen or broken electric wire may receive an electric shock, may be burnt may be cut by the wire or may be knocked down.

First aid treatment.—If any wire be touching the injured person it must first of all be removed as above directed If the person be severely cut by the wire or burnt, or otherwise severely injured but remains conscious he may be removed to the hospital If apparently dead the person should be laid flat on his back with the head low and " artificial respiration " should be immediately resorted to and should be kept up until medical assistance arrives The limbs may also be rubbed and cold water may be applied to the head but no stimulants of any kind should be administered.

The plague epidemic is rapidly declining This week only 4214 deaths have been recorded, as against 5498 during the previous seven days. For the corresponding week last year only 1658 deaths were returned from plague. The details are Bombay city, 166 , Bombay districts, 260 Karachi 59 Madras Presidency 16 Calcutta, 132 , Bengal 107 United Provinces 116 , the Punjab 3226 , Mysore, 116 and Kashmir 15. The famine is still further spreading An increase of 9000 in the number of those under relief has taken place and the total now stands at 457,760.

Cigarette smoking seems to have taken hold of the natives of India. There has been a very large increase in imported tobacco chiefly in the form of cigarettes. The weight of cigarettes imported has been considerably over 1 000 000 pounds. These have come chiefly from the United States and Great Britain. It is common now to see natives smoking American cigarettes and boxes of them are being regularly hawked about the towns.

Certain recent schemes concerning the opium traffic in China give special interest to the peculiarities of Indian opium. It is said that the high value of Indian opium—viz. about three times the cost of its production is due to its mildness when smoked and that it contains a low proportion of morphine as compared with the Turkish variety

June 7th

MANCHESTER.

(FROM OUR OWN CORRESPONDENT)

Manchester Royal Infirmary

THE report of the board of management of the Manchester Royal Infirmary recommending that the infirmary should be rebuilt on the present site has been issued and a special general meeting of the trustees is to be held on July 22nd to receive consider and if approved, to adopt, the same and to authorise the board to proceed with the work of reconstruction. The need for enlargement may be illustrated by a conversation that took place at the meeting of the board of guardians on June 23rd. It was stated that a man who had been injured was refused admittance for lack of room and was sent to the Crumpsall workhouse hospital The view of the chairman of the guardians and others of the board seemed to be that beds should be reserved for cases of exigency as, indeed they are, and one of the guardians asked If the Royal Infirmary is not to receive poor people what does it exist for? forgetting apparently that the reserve beds may all have been filled. It was so in this case, as appears from the answer to a letter from the guardians, which said that the whole of the beds, including those reserved for emergencies, had been filled, and the patient had been sent to the Crumpsall hospital contrary to all intention through an oversight of one of the resident officers It goes on to say that " such regrettable cases afford further evidence of the necessity for the proposed enlargement of the hospital." According to the proposed plans the beds for patients will be increased from 292 to 452 at an estimated cost of £200,000. As one of the local papers puts it, the battle of the sites is over and as no millionaire has come forward to help the city to purchase the infirmary area the idea of a superb art gallery and reference library on the Piccadilly site, with a modernised infirmary near the Owens College, must be abandoned Millionaires unfortunately do not seem to be kept in stock." It is felt by many to be a misfortune that for an indefinite future the principal hospital of Manchester will be fixed in the centre of a dense town, on a cramped and insufficient area, surrounded on all sides by streets dusty and noisy with never-ceasing traffic, and penetrated from time to time with fog the pungency of which is most irritating and injurious. But though this is so all credit must be given for a sincere and strenuous effort to meet what seems an unfortunate necessity

The Infirmary and the late Dr Leech

At the close of the ordinary business yesterday the board of the Manchester Royal Infirmary received a deputation of medical men from the Leech Memorial Committee asking them to accept a portrait of the late Dr Daniel J Leech similar to one recently presented to the Owens College The deputation consisted of Mr Walter Whitehead, Dr J Dreschfeld Mr Joseph Collier Dr A Hill Griffith Dr Judson S Bury and Dr E. M. Brockbank. Mr Whitehead said that he had been asked to make the presentation because he had known Dr Leech longer and more intimately perhaps than any one present. They were fellow-students and elected to the staff of the infirmary on the same day He spoke truly and generously of Dr Leech s self sacrifice for the sake of medical education and the public welfare of his devotion to work, of his simplicity of character and his candour Few persons " he said are aware how much he did to help on the careers of medical students who were crippled in funds and who but for his generosity would have had to suspend their medical education. As Mr Whitehead said in asking the board to accept the portrait, it can, however excellent but inadequately represent to future generations the noble and unselfish life of the late Dr Leech. Sir F Forbes Adam chairman of the board, said that he accepted on behalf of the board of the infirmary, with very great pleasure indeed the replica of the portrait of the late Dr Leech and he paid a high tribute to his character and the great services that he had rendered to the infirmary

Royal Infirmary Appointments

At the meeting of the board of management of the Manchester Royal Infirmary yesterday Sir F Forbes Adam presiding Dr W S. V Stock was re-appointed resident medical officer for a year from July 8th and Dr H. B. Wyman was appointed assistant medical officer at Cheadle for a year

A Manchester University

The Convocation of Victoria University consisting of graduates, discussed the question of separate universities for Manchester Liverpool and Leeds at a meeting held on June 23rd at Owens College. The attendance was large and a long debate took place after which Professor Tait s resolution was passed —

> That under existing circumstances Convocation is of opinion that the cause of higher education and the interests of the constituent colleges of the University will best be served by the adoption of the course recommended by the University Court.

This course wa it may be remembered that of disruption The resolution was carried by 137 votes to 87 The discussion was marked by a good deal of animation and the philosophic doubts on one side or the other were not always expressed without acrimony The presence of lady graduates did not quite avail to soothe the savage breasts " for when one lady proceeded to speak at length against disruption in seconding an amendment moved by Professor Smithells she was met by cries of Vote and Time, and she had great difficulty in continuing her remarks," so that another lady graduate observed reprovingly Those are university manners Perhaps it may be hoped that in time this feminine influence may soften the ruggedness of northern culture. So far as public opinion can be judged by the leaderettes in the two chief Manchester papers it is in favour of an independent as against a federal university but the question would probably have remained dormant, so far as Manchester and Leeds are concerned had not Liverpool first felt the stirrings of ambition. Whether the cause of higher education and the interests of the constituent colleges will be best served by federation or disruption the future may determine. Able men hold opposite views but it would be difficult, if not impossible for Owens College whatever the result may be, not to take up the challenge of Liverpool. It may seem ungracious that Leeds should be as it were cast off against her will, but she has energy enough to face the future without fear

Salford Sewage Works

One is almost weary of the adjourned actions brought by the Mersey and Irwell Joint Committee against the corporations of Manchester and Salford for their delinquencies as regards sewage purification At the last hearing however on June 23rd his Honour Judge Parry was able to congratulate Salford on the great progress that had taken place since his last visit to the works. Mr Strachan, the consulting engineer thought that 12 months ought to be allowed for the completion of the present scheme for the treatment of the sewage The effluent, he said, was now satisfactory, but he would like to see the filter at work for three months before giving a final opinion His Honour said that it would remain to be seen whether the actual number of filters when completed would be sufficient for the needs of the neighbourhood, and attention should be given as to how far the present provision would be sufficient for future needs There seems hope, therefore, that Salford may overcome its sewage difficulties

County Constabulary and Charities

The Bury division of the Lancashire County Constabulary held its annual sports recently and devoted the profits, amounting to £107 7*s* 9*d*, to various charities The Bury Infirmary receives £45, the Ramsbottom Cottage Hospital £10, and three sick nursing associations £10 each There are also donations to the Society for the Prevention of Cruelty to Children and the Society for the Prevention of Cruelty to Animals, to the Police Orphanage, Harrogate, and to the police poor box This is a good example, and might, perhaps, be followed more frequently than it is by the cricket and football clubs whose matches are watched by thousands

July 1st

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

University of Dublin

A MEETING of the Senate of the University of Dublin was held on June 30th to elect a member of the council for "Classis Tertia." Professor Edward Hallaran Bennett was unanimously elected

Death of John Harrison Scott, M B Dub , F R C S Irel.

The death is announced at the early age of 40 years of Dr John Harrison Scott, formerly of Fitzwilliam square, Dublin Dr Scott was in bad health for some years but was formerly well known in medical circles in Dublin where he filled the posts of surgeon to the Adelaide Hospital and of medical officer to St James s Gate Brewery and other important appointments

Vacant Chairs in Queen s College, Belfast

The Dunville professorship of physiology and the chair of natural history in Queen's College, Belfast, are both vacant and the appointments rest with the Crown Candidates must send their applications to the Under Secretary to the Lord Lieutenant of Ireland, Dublin Castle, on or before July 5th The endowment of the chair of physiology is £250 and the class fees in the session 1900-1901 (the last reported) were £308, while the endowment of the professor ship of natural history is £282 and the class fees for 1900-1901 were £190 It should be added that both of the former professors in these subjects held examinerships in the Royal University, which increased the value of their annual incomes

Scale of Fees in Irish Dispensary Practice

It has been decided to appeal in the case of Mr J W Olpherts (medical officer of Downpatrick Dispensary District) *v* Downpatrick Union, against the decision of the county court judge to the effect that the scale of fees for extra-professional assistance fixed by a board of guardians and sanctioned by the Local Government Board cannot be exceeded even though the medical practitioner concerned had not agreed to the scale and had stated when his services were requisitioned what his fee would be The Irish Medical Association is anxious that every effort should be made to obtain a reversal of this decision which affects every medical practitioner in Ireland, whether in the Poor-law service or not The Irish Medical Association will bear the costs in this appeal case

The Royal University Commission

Mr F H O'Donnell, M.A. (a Royal University graduate), has published a letter with statements in reference to his treatment when on May 22nd he tendered himself for examination before the Royal Commission on University Education in Ireland, which certainly demands an early and full explanation. He denies the correctness of the official report of his appearance which has been sent to him, and publishes a corrected report of what took place which he has sent to the secretary of the commission When he informed the Commissioners on appearing before them that he had 20 pages of notes on very important points and that he was prepared to read them or speak from them (the usual course adopted by witnesses) the chairman, Mr O'Donnell writes, said "The commission does not think it necessary, we have your book and the summary of your evidence, and I do not think we need trouble you further" On Mr O'Donnell protesting against being suppressed, he was silenced by the commission, the chairman exclaiming "Call the next witness Call the Lord Chief Justice" The publication of this letter of Mr O'Donnell has produced a bad impression The newspapers are asking why in the first place did the commission decide to ignore Mr O'Donnell's offer to give evidence, a course it persisted in for a long time Was it owing to public press criticism that it afterwards agreed to hear him, and having done so why did it decide when it allowed him to appear before it that he should not be permitted to say anything?

Small pox in Belfast

Only one new case of small pox has been admitted into the Union Fever Hospital, Belfast—that of a man who had been in several lodging houses and who had spent during the period of incubation a few days in the Royal Victoria Hospital as he was suffering from hæmorrhoids It was fortunate that no surgical operation was done, as shortly after leaving the hospital the rash of small pox appeared.—The new hospital, erected in a period of 20 days at Purdysburn by the public health committee, has been completed and is now ready for patients The hospital, a one-storeyed one, is built of wood and iron with a corrugated iron sheeting and has been constructed for 32 patients It consists of four large wards The most complete arrangements have been made in connexion with ventilation, heating, bath, and sanitary arrangements There is an excellent administrative block with nine rooms for the medical officers and nurses who have charge of the patients It is connected with the hospital by a covered passage 100 feet long by four feet in breadth At a radius of 100 feet from the buildings strong corrugated ironwork is being put up and a small mortuary has also been constructed apart from the main building This new small pox hospital, complete in every respect, is a great addition to the medical institutions of Belfast Unfortunately the residents around Purdysburn object to its location there very strongly and have held a public meeting and again protested on the ground that it was too near (nearer than the regulations of the English Local Government Board would permit) to a public school and to other houses in the neighbourhood Mr T W Russell, M P, has asked a question in the House of Commons on the subject.

Royal University Graduates' Association

The third annual meeting of the Royal University Graduates' Association, a body embracing 600 graduates representing all professions (clerical, medical, legal, engineering, and teaching) was held in Belfast on June 28th From the report (presented by Dr R. W Leslie, one of the secretaries) and the speech of the chairman (Dr W A McKeown) who is the president of the association, it appears that the association is in a most flourishing condition Special reference was made to the sittings of the University Commission (and the council of the association believes that the case for the establishment of sectarian and petty universities in Ireland has been damaged past hope of recovery), to the victory achieved by the association in the recent election of representatives on the Senate of the Royal University, all pledged to the appointment of extern examiners, to the refusal of the commission to hear Mr F H. O'Donnell M A, and to the policy of the association in reference to the university question, which is, first, reorganisation of the Royal University on an academic representative basis and the abolition of Crown nominations, and, secondly, the severance of the connexion of the Crown with the Queen's Colleges and their government by a body representing various and local academic interests Dr. McKeown was unanimously re elected president of the association for the ensuing year

Scandals at the Competition for the Post of Hospital Physician

THE scandals at the yearly competitions offered by the administration of the Assistance-Publique for the post of hospital physician or surgeon grow worse and worse and are the subject of much comment even in circles outside the medical profession. Only a month ago there was a scandal of which I have already spoken.[1] The recent competition for the posts to be occupied by six physicians has been marked by most regrettable incidents which have naturally been made much of in the lay press. Those incidents were such that two members of the jury M Albert Robin and M. Henri Huchard, wrote a strong letter of protest to the Director of the Assistance Publique which appeared in the public press. On Saturday June 14th, when the results were published and before the successful candidates had been nominated M Robin and M. Landrieux sent in their resignations. M Huchard had already sent in his All these scandals have been the cause of acute comment among the public, although they cause no surprise in medical circles, where the undesirable methods which obtain in the public competitions have been long known. The hospital physicians and surgeons as a body are annoyed at the action taken by three of their members, and at the meeting of the Hospitals Medical Society which followed on the competition the reception of M Robin and M Huchard was very cool. As, however both of these gentlemen are of considerable scientific eminence they are indifferent to this action and their bold, independent attitude is most favourably commented on by the great body of medical men as a step towards the reform of the present methods in vogue in public competitions.

Alcoholic Drinks

About a year ago in the course of a Parliamentary discussion upon the law as to drinks, a Socialist deputy Dr Vaillant, proposed that the Academy of Medicine should be requested to make out a list of alcoholic drinks such as liqueurs, apéritifs, and the like which contain essences dangerous to public health with a view to interdict the manufacture or sale of such As the Minister concerned did not accede to this request the Academy has at last sent into Parliament a report on its own account. M. Laborde has published the report in the name of the commission appointed by the Academy The report states that the essences used are very poisonous. Synthetic essence of anisette contains a quantity of hydrocyanic acid The inhalation of a little of this essence from an open bottle containing it causes grave syncope and a feeling of illness lasting for several days. Chartreuse is very poisonous and contains 13 substances which can bring about serious effects. Vulnerary contains 15 very poisonous substances. The genuine vegetable essences are bad enough but these are not used now and the essences are all made with synthetic flavourings which are even more poisonous than the genuine vegetable essences Gin (*genièvre*) contains a poison and bitters are also very dangerous. M Laborde proposes that the sale of the following should be absolutely forbidden except for medicinal use absinthe and its compounds, bitters vermouth noyeau, chartreuse, gin, and vulnerary It is proposed that the authorities shall forbid the manufacture or sale of these drinks as containing substances harmful to public health. If this is not done the laws existing on the matter should be rigorously applied

The Physiological Education of Deaf mutes

At the meeting of the Academy of Medicine held on July 17th M. Laborde gave an account of the method employed by M. Dussaud in the education of deaf mutes. M Laborde showed a number of patients in whom M. Dussaud's method had brought about excellent results. The principles are as follows the child at the age when speech would normally begin to develop is put through a series of exercises addressed to the ear with a view to developing the auditory function the coöperation of which is at the outset at least necessary for the acquirement of speech He uses an apparatus devised by himself for amplifying sounds called the *amplificateur audiométrique* It is a kind of loud speaking phonograph It is of great value especially at the beginning of the educational course to make use of musical sounds as well as spoken sounds. M. Laborde showed nine children who had been enabled to speak by means of this method

Apparatus for Anæsthesia

At the meeting of the Therapeutic Society held on May 28th M. de Crésantignes showed an apparatus for administering volatile anæsthetic agents such as the bromide or chloride of ethyl. The apparatus consists of a mask which hermetically seals the mouth and nose of the patient. This mask leads into a vessel which collects the air expired by the patient and by sinking in at the moment of inspiration returns it to him Thus no loss of anæsthetic occurs and the patient gets no air which is not saturated by the anæsthetic. Owing to this there is no period of excitability

A New School of Hygiene

The municipality of Marseilles has just concluded some negotiations with the Minister of War with regard to the creation of a school of colonial hygiene at Marseilles. The municipality has offered to place at the disposal of the Minister the left wing of the Pharo together with certain of the surrounding buildings. When the school is fitted up there will be accommodation for 100 pupils. The municipality has further promised to bear the cost of the work necessary for getting the buildings ready for occupation which will amount to about 150,000 francs. This sum will include the cost of a new block and the doing up of rooms to serve as class rooms together with a theatre for lectures and demonstrations

(FROM OUR OWN CORRESPONDENT)

Statistics of Hay Fever

DR. THOST a specialist in nasal and laryngeal diseases in Hamburg has been carrying out a collective investigation into hay fever and its causes. The investigation includes 400 cases partly from his own practice and partly collected among the members of the Hay Fever League an association of sufferers from hay fever from Germany Austria, Holland, and Switzerland who in May and June every year meet at Heligoland and patronise any research into the etiology and therapy of this disease. Dr Thost's report which is published in the *Münchener Medicinische Wochenschrift* states that to produce hay fever in a person three things are necessary a specific cause a local disposition of the mucous membrane of the nose and the respiratory organs and a general disposition of the nervous system. As to the specific causes it was found by the statements of the patients that hay fever was brought on by grass flowers in 89 cases by pollen in 61 cases by hay in 32 cases by lawns in 18 cases by flower-dust in 59 cases, by the smell of flowers in 17 cases, by flowering plants bushes and trees in 30 cases, and by corn flowers cornflour and cornfields in 33 cases. Many patients had an idiosyncrasy with regard to certain flowers one patient was attacked by hay fever in winter time because he had cultivated hyacinths in his room Apart from flowers and their pollen the following causes were said to produce attacks of hay fever dust in 86 cases and smoke stone dust and flour dust once, respectively , bad smells in 10 cases tobacco-smoke in 13 cases smell of horses twice and a draught of air in seven cases A railway journey is given as the exciting cause in 56 instances sunlight 69 times , heat, 43 times dry air 18 times bad air five times change of temperature 13 times fog once , a stay in fresh air 16 times. Other less frequent causes are mental work muscular strain and drinking , eight patients said that their attacks were due to neurasthenia and one patient even said that the attacks occurred when she thought of hay fever whilst in another case an attack happened when the patient thought of a cornfield. Of still more peculiar causes one patient may be mentioned who was attacked by the disease when he combed his hair another when covered by woollen textures a third by furs and a fourth when cats were in his room. It is however remarkable that only three patients alleged catching cold to be the cause of the illness. Pollen is generally believed to contain the irritant agent by which the fits are produced A great many examinations of the nasal mucosa however showed that pollen grains were present in the nasal mucus in a few instances only one patient even reported that he was able to snuff plenty of pollen without catching hay fever on the other hand it was rather striking that so many patients accused the smell of certain flowers as producing the fits so that possibly a volatile agent may be the cause. As to the nature of the disease being eventually discovered to be parasitic the bacteriological examination of the nasal mucus performed at the Hamburg Hygienic

---

[1] THE LANCET May 31st 1902, p 1563.

Institute showed a white staphylococcus, which was present in hay fever patients exclusively, this staphylococcus accordingly was inoculated on the mucous membrane of some medical men who agreed to this experiment but the results were negative Concerning the local disposition it was found that the majority of patients previously to their having caught the disease had suffered from catarrhal affections of the nose and the respiratory organs and that a great irritability of the olfactory organs was present. As to the general disposition it has been known for a long time that peasants though very much exposed to the above-mentioned alleged exciting causes are seldom attacked, while inhabitants of the great towns often are. As a rule the patients belong to the upper classes and those engaged in mental work are specially liable. Dr Thost's statistics, indeed, show that a great number of patients belong to learned professions Sometimes the first fit occurred immediately after a great mental strain or over exertion, sometimes as a sequel to some exhausting disease, such as scarlet fever or diphtheria. Gout, which in England is alleged to be connected with hay fever, was found to be present in 30 out of 400 cases only Hay fever having increased during the last years Dr Thost suggests that there may be eventually a connexion with influenza, this suggestion being confirmed by the fact that 187 of the patients had suffered from this disease As to the symptoms the statistical research showed that 266 patients were affected with real asthmatic fits, 134 with catarrhal symptoms only, and that about 75 per cent besides complained of general uneasiness Dr Thost finally gives a report of the therapeutic measures and states that there is no safe cure for the disease in every case, the Hay Fever League recommends snuffing tobacco, some cases were benefited by cauterisation of the nasal mucosa, others by the local application of narcotic compounds, others by the administration of iodine, quinine, &c There exists only one remedy against hay fever—namely, the stay in a place without vegetation, for Germany the island of Heligoland where members of the league are accustomed to stay in the spring, is especially suitable

The Struggle against Venereal Diseases

As already announced in these columns[1] a German Society for the Repression of Venereal Disease is in course of formation A provisional committee, consisting of Dr Blaschko of Berlin, *Professor Neisser of Breslau*, Professor Lesser of Berlin, Dr Galswoky of Dresden, Professor Wolff of Strasburg, and Professor Kirchner of Berlin, has issued letters to the medical profession, to the committees of sick clubs, philanthropic societies, insurance companies, &c, to invite them to become members and to make known the objects of the society The letter is signed by the above executive committee and also by about 200 medical men and others and even by some philanthropic ladies It is said in the letter that tuberculosis, alcoholism, and syphilis are the three scourges of the human race, tuberculosis and alcoholism have begun to be combated on a large scale by the united efforts of both medical and lay circles, as to syphilis nothing of the kind hitherto has been done The result is that the frequency of venereal diseases, their dangers, their spread, and the means of prophylaxis, are unknown to all except the medical profession Besides, mistaken ideas of modesty oppose public discussion of these questions and any enlightenment of people and thus aid the spread of syphilis Although the total abolishment of prostitution is not possible at present, there is nevertheless a good deal to be done in diminishing the injury done to the health of the entire nation by this plague The new society will follow the example of, and be in connexion with, the Société Internationale de Prophylaxie Sanitaire et Morale founded in 1899 at Brussels It will try to gain as many members as possible from all classes of society and public meetings will be held, addresses delivered, and popular essays distributed concerning sexual hygiene, moreover, the society will try to induce the Government and Parliament to alter the laws on prostitution, on the exclusion of venereal patients from relief by sick clubs, &c The meeting to constitute the society will be convoked this autumn at Berlin

Statistics of the Prussian Universities

At the 10 universities of Prussia 17,880 students have matriculated for the summer semester Berlin has 5676, Bonn 2091, Breslau 1827, Halle 1727, Göttingen 1371, Marburg 1362, Kiel 1156 Königsberg 968, Münster 877, and Greifswald 825 students The greatest number (7679) belong to the philosophical faculty, next comes the legal faculty with 5053, the medical faculty with 2928, and the theological faculties (both the Protestant and Roman Catholic) with 1289 and 941 students respectively The medical students are distributed as follows Berlin, 1018, Kiel, 439, Greifswald, 237, Bonn, 235, Breslau, 228, Marburg, 210, Königsberg, 201, Halle, 198, and Göttingen, 162. 657 ladies are admitted to the lectures at the universities, their regular matriculation being at present impossible under the university by-laws of Prussia In Berlin there are 370, in Bonn 106, in Breslau 65, in Göttingen 38, in Königsberg 36, in Halle 28, in Kiel 10, and in Marburg 4 lady students respectively The number of foreign students is 1440, of whom 888 are matriculated at Berlin, 162 at Halle, 89 at Göttingen, 88 at Marburg, 67 at Bonn, 62 at Königsberg, 47 at Breslau, 25 at Greifswald, and 16 at Kiel Of the 888 foreigners of Berlin University 323 are Russian, 102 Austrian, 66 Swiss, 47 Hungarian, 36 British, 20 Bulgarian, 17 French and Roumanian respectively, 15 Italian, 15 Scandinavian, 15 Greek, 14 Servian, 11 Turkish, 10 Luxemburgian, 7 Dutch and Belgian respectively, 3 Spanish, and 2 Danish, 103 come from America, 52 from Asia, 2 from Australia, and 1 from Africa.

Dues payable to the Medical Chambers

The law empowering the medical chambers to impose certain dues on the medical men of each district does not commend itself to those members of the profession who are not engaged in practice but devote themselves exclusively to scientific pursuits It will be remembered[1] that some months ago the medical men holding appointments in the laboratories and other scientific departments of the University of Berlin petitioned their medical chamber to exempt them from this taxation, but their petition was unanimously rejected Another class of medical men who complain loudly of the taxation are those who, being qualified practitioners, have either taken up some other profession or else live on their income without engaging in practice The law makes no provision for their exemption either from taxation or from the jurisdiction of the courts of honour, so that it is within the limits of possibility that a man who holds a qualification to practise medicine b nevertheless follows some totally different occupation ma become answerable to the court of honour of his district f some act that he has committed Such a case, it is tru has not yet occurred in actual fact, but if it did th medical chambers might find themselves in the dilemm of having to adjudicate upon questions with whic they had no competent acquaintance A discussion too place recently in the Prussian Herrenhaus (House of Lord relative to the liability of holders of medical qualifications t pay dues to the medical chambers in the cases where suc qualifications were to all intents and purposes inoperati through their holders not practising It was introduced b Dr Freiherr von Lucius, the holder of a medical qualifica tion and formerly Minister of Agriculture, he proposed a alteration in the law relative to the medical chambe so that only medical men in actual practice shoul be required to pay dues, and that only incomes derive from medical practice and not from other sources shoul be liable to assessment. The Minister of Educatio whose department includes matters bearing on the medic profession, remarked on the inadvisability of making alter tions in a statute of such recent date, but said that th provincial authorities who have the supervision of the medic chambers had been requested to induce the chambers grant a reduction of 50 per cent on the dues payable b holders of qualifications who are not engaged in practic The periodical press, both medical and non medical, have this connexion directed attention to the fact that the la contains no provision by virtue of which the holder of medical qualification can succeed in divesting himself of th position and responsibilities of a member of the medical pr fession In the legal profession the case is otherwise, for lawyer is at liberty to make a declaration that he no long desires to remain on the register, and on the removal of h name from the register he ceases to come under the jurisdi tion of the legal chamber An alteration in this sense obviously required in the laws affecting the medical pr fession

June 30th

[1] THE LANCET Jan 25th 1902, p 268

NEW YORK.

(FROM OUR OWN CORRESPONDENT)

Spitting in the Street and Public Places Forbidden.

THE New York City Board of Health has amended its gulations so that spitting upon the side walks and upon e floors of public buildings, the halls of tenement houses otels and lodging houses theatres, halls, and other places r buildings in which there are public assemblages and upon e station platforms or stairs of elevated or steam railroads rry houses, or ferry boats, is now unlawful. This action as taken as the result of a communication from Dr erman H. Biggs, the medical officer who says that he elieves that the time has now arrived when the pro isions of this section should be extended so as to nclude side-walks halls of tenement houses stations, nd platforms of steam railroads and all other build gs in which there are public assemblages He asserts hat the grave feature of this pollution of public places of sembly and public conveyances is the inevitable transporta on of this always objectionable and frequently dangerous aterial on the footwear and on the clothing and particu rly the skirts of women into private houses where in the bsence of the most perfect system of ventilation and cleans ng it is a constant menace to the welfare of the occupants hose attempts to maintain salubrious conditions in their homes are rendered in an important particular futile through e vicious practices of others in public places.

Enforcing Payment for Medical Services to Patients in Hospitals

Dr George R. Fowler of Brooklyn who is attached to the rooklyn Seney and German hospitals in the capacity of hief visiting surgeon has brought suit against a number of ersons who have received professional services at his hands nd who have refused to pay on the ground that they are harity patients This suit is brought with the hope that it ay bring to a stop the alleged imposing upon physicians nd hospitals by persons who are able to pay for their treat ent. Dr Fowler says that these are test cases by which he opes to vindicate a principle that is abused in every hospital. or years certain persons have imposed upon physicians and ospitals by claiming that they are too poor to pay for angerous and skilful operations The practice became so eneral that he commenced an investigation and found that he suspicions were correct feeling that his professional ervices and skill were worth something he remitted bills to hose whom he found well able to pay and in some of these ases the life of the patient had been saved. He also felt hat the profession at large ought to put a stop to this system he imposition upon them by a class of people posing as oo poor to pay for benefits received, many of these proved o be far better off than those unfortunate people for whom he hospitals are maintained in their free departments. hese suits have been sustained by the courts

The Value of the Identification of Criminals.

The Bertillon system of identifying criminals as used in the tate prisons of New York is shown by Mr C. V Collins, uperintendent of State prisons in his last annual report. As n aid to its maturely framed system of prison administration nd criminal supervision the State *established in 1888,* and till maintains, a Bertillon *system of identification* of riminals which is the largest in America and is undoubtedly the most perfectly equipped one in the world. This bureau contains 43,000 cards, each representing a criminal who has been confined in one of the penal institutions in this State at some period since 1896. It also contains 1289 cards received from the penal institutions of other States during the year just passed Since September 1900 it has been the central bureau both for the penal institutions of the State and for those also of 17 other States and of Canada It is believed that the records of a majority of the persistent criminals of this State are now on file in this bureau, and as the cards from other States increase in number the scope of observation and detection will be gradually enlarged, and in the course of a few years the bureau will be in a position to furnish the records of nearly all of the professional criminals on this continent. The State is not, however, receiving the full benefit which it might from this bureau, because few of the police departments of our cities and none of the county sheriffs have the equipment necessary for measuring photographing and describing criminals arrested by them. The efficiency of the system is shown by the fact that by its use 2438 criminals have been identified in the five years that it has been in operation in the State of New York.

The American Congress on Tuberculosis

The third annual meeting of the American Congress of Tuberculosis and the Medico Legal Society was held on June 2nd 3rd, and 4th at the Hotel Majestic, New York City A large number of delegates were present from the United States, as well as representatives of Canada, Mexico, and Central and South America The Government of the United States was represented by officers of the army navy, and Marine Hospital Service. The presidential address was delivered by Dr Henry D Holton of Vermont. The first discussion was on 'Preventive Legislation and a motion was adopted declaring it to be the duty of every government municipality and individual citizen to adopt organised measures for lessening the spread of a disease which was causing directly or indirectly probably one-fifth of the total deaths in almost every country of the world. Dr L. L. Kinyoun opened the discussion on Bacteriology and Pathology and expressed the belief that bovine and human tuberculosis were interchangeable He said that notwithstanding the long years of bacteriological research no serum had been discovered which would neutralise the tubercle bacillus and the disinfection of the patient's surroundings remained the most important precaution. Dr H Edwin Lewis read a paper on the Importance of Individual Predisposition in the Development of Tuberculosis. He disagreed to some extent with the views expressed by Dr Kinyoun and pointed out that attendants in tuberculous hospitals rarely contracted the disease through infection. He was of the opinion that personal resistance to the bacillus was to be strengthened by better habits of living rather than by sanitary *precautions* Dr William S. Macgill of the Carnegie Laboratory asserted that the popular belief that bacterial virulence was the chief cause of tuberculosis was an error The present contradictory state of opinion he attributed to the unsatisfactory results of laboratory experiment, which had been directed toward the destruction of tubercle bacillus while the true cause of tuberculosis seemed to be a higher form of micro-organism The closing session of the meeting was the most instructive and interesting The subject discussed was the Veterinary Aspects of Tuberculosis. Dr Adami the well known Professor of Pathology at McGill University Montreal opened the discussion in a very eloquent speech the first part of which dealt with tuberculosis of cattle from a commercial standpoint. He said "Is the existence of tuberculosis among livestock a menace to that industry in this country? Undoubtedly it is and that not so much because here in America the herds are already extensively affected as because of its great tendency to spread. Nevertheless in the Eastern States its ravages are already serious enough With cattle as with man it may be laid down that the more the existence is indoors the less life is led in the open air the more susceptible are the individuals to this disease There have been numerous instances in the Eastern States in which every member of a dairy herd has been found to be a victim of tuberculosis. On the other hand the Western ranch herds which live almost entirely if not wholly, in the open *are with rare exceptions exempt. It may be asked why if bovine tuberculosis has been known for centuries* it is only of late that it has spread to such an alarming extent The answer would seem clearly to be that the spread is coincident with the greater development of the cattle industry and especially of the ease of transportation. In the old days the movement of cattle was as nothing compared to what it has become during the past 70 years it is the frequent interchange of beasts and frequent introduction of new and tainted animals into the herds that has wrought the damage, a subsidiary influence being undoubtedly the general attempt to improve the milk giving qualities by the introduction of highly bred and at the same time highly susceptible animals. It is to the commercial and monetary significance of this spread that I would specially draw attention. Affecting the livestock and industry it affects what is far and away the greatest industry of the country Only two-fifths of the population of the United States live in towns of 25,000 inhabitants or more than three-fifths gain their living from the soil. The invested capital in the live stock industry exceeds that of any other in this country What I wish you to consider is the enormous loss that would accrue to this country with its millions of cattle if only 1 per cent. of the animals slaughtered were the victims of advanced tuberculosis" The prospective loss is so great that this is immediately seen to be a national concern. Professor Adami thinks that the time to act is before the disease gets "out of hand", he is of the opinion that everything points to the fact that taken in time the eradication of tuberculosis from a herd or from a district need not be a costly matter either for the individual or for the community More particularly, he says, the employment of Bang's method of isolation of reacting animals affords us a means of rendering a herd wholly free from disease in the course of from three to five years Dr Adami's views expressed the general attitude of the congress

June 22nd

Obituary.

JOHN WICHENFORD WASHBOURN, C M G , M D , F R C P LOND , F R C S ENG ,

PHYSICIAN TO GUY'S HOSPITAL AND TO THE LONDON FEVER HOSPITAL.

DR. JOHN WICHENFORD WASHBOURN, C M G , who died at Tunbridge Wells on June 20th, was the younger son of the late William Washbourn of Gloucester and traced his descent through the Washbourns of Washborne and Wichenford, Worcestershire, to the Sir Roger Washbourn mentioned by the Heralds in their Visitation of Worcestershire in 1370 After a long and arduous winter's work, during which every spare moment was devoted to experimental research in preparation for the Croonian lectures of the Royal College of Physicians of London (which he was to have delivered this month), Dr Washbourn was seized with an attack of influenza which at first appeared to be no more serious than any of the many mild attacks from which he had suffered in recent years, and, in fact, at the end of a week, throughout which he had pursued his usual occupations, he expressed himself as almost well. At this stage, however, a sudden rigor warned him of the necessity for caution He at once took to bed and some 10 days later a collection of serous fluid was removed from the right pleural cavity—a proceeding which was twice repeated At one time he appeared to be gaining ground, but the improvement was transitory, and about ten weeks from the commencement of his illness it was decided to try the effect of change He was accordingly removed to Tunbridge Wells, but a week later the diagnosis of miliary tuberculosis was made, which disease proved fatal in another fortnight, just two days before his thirty-ninth birthday

Born at Gloucester in 1863, he was educated at King's College Gloucester, Guy's Hospital, the University of Vienna, and the University of Königsberg His student career at Guy's from his entry in 1880 was an exceptionally brilliant one, his enthusiasm for the profession he had adopted and his boundless capacity for work at once marking him as a student of the highest promise. At the Intermediate M B examination of the London University in 1883 he gained the gold medal and exhibition in chemistry, and at the Final M B examination in 1886 the University scholarship and medal in medicine and the gold medal in forensic medicine, together with honours in the B S He took the Membership of the Royal College of Surgeons of England in 1885 and the Fellowship in 1888 , the Membership of the Royal College of Physicians of London followed in 1889 and he was elected to the Fellowship in 1894 In 1888 he was appointed demonstrator of anatomy at Guy's Hospital, in 1889 assistant physician to the London Fever Hospital, in 1890 assistant physician to Guy's Hospital to the duties of which was added the charge of the electrical department, full physician to the London Fever Hospital in 1892, and joint lecturer in Physiology to Guy's Hospital in 1891. In 1890 he instituted and organised the bacteriological department of Guy's Hospital, to which he was appointed lecturer in 1898 He married, in 1893, *Nellie Florence, daughter* of the late Mr William Freeland Card, of Greenwich Hospital School , a year later, however, he sustained a heavy blow in the death of his wife, leaving him with an infant daughter In February, 1900, he proceeded to South Africa, and from that date to June, 1901, he was consulting physician to the Imperial Yeomanry Hospital, first at Deelfontein and afterwards at Pretoria. He was gazetted C M G in 1900, and consulting physician to His Majesty's forces in South Africa in 1901. Immediately after his *return from South Africa* he filled the presidential chair in the Section of Pathology and Bacteriology at the annual meeting of the British Medical Association, and his opening address, dealing in a masterly manner with the infective diseases prevalent in the South African army will be fresh in the memory of all who were present on that occasion

During the last five or six years Dr Washbourn was actively engaged in consulting work, and although the success which he had already attained augured well for the future, still he was perhaps more widely known by his brilliant work as a bacteriologist. In the early part of 1888 he worked under Professor von Baumgarten in the University of Königsberg, and in 1890 he commenced, in association with Professor Gruber of Vienna, those exact researches into the etiology and pathology of pneumonia which were carried on uninterruptedly until the commencement of his fatal illness and which have rendered his name familiar throughout the scientific world. His contributions to the life history of the pneumococcus, either alone or in conjunction with workers trained by himself and enlisted in the work, were many and important, the chief of which were an examination of the varieties of the diplococcus pneumoniæ and the evolution of an extremely ingenious method of accurately estimating their virulence , whilst as the result of his work in this direction he was enabled, after many unsuccessful attempts, to obtain from horses an anti-pneumococcic serum of such high potency that he was encouraged to employ it therapeutically in the treatment of cases of acute pneumonia. He recorded the results in the *British Medical Journal*, February, 1897, some months before Pané of Naples independently published details of an anti-pneumococcic serum prepared from donkeys and goats., Although the result of the therapeutic use of Washbourn's anti pneumococcic serum was not an unqualified success, it was so encouraging that we have no hesitation in saying that his death materially delays the advent of a potent remedial agent in pneumonic processes But his work was by no means confined to this one subject. On the introduction of anti diphtheritic serum he at once commenced an investigation into its clinical applications and the communication of his results to the Clinical Society of London in 1894 (in conjunction with Dr E W Goodall and Mr A. H. Card) drew from the presidential chair a warm commendation of their value and helpfulness, and there is no doubt did much to encourage the employment of the antitoxin in cases of diphtheria

In the field of preventive medicine Washbourn will be chiefly remembered on account of the part which he played in the elucidation of the causation of the Maidstone typhoid fever epidemic of 1897, when he was called in to advise the local authorities The result of his bacteriological examinations of the various sources of the local water supply and the inferences which he drew therefrom, proved beyond doubt that the pollution had occurred in the Tutsham in Field spring , and that the action taken by the local authorities upon his recommendation was fully justified was borne out by the result no less than by the verdict of the subsequent Local Government Board inquiry Washbourn was an ideal research worker, possessed of an infinite capacity for taking pains and a keenly critical appreciation of the relative value of his results, tempered with a healthy scepticism which refused to believe even the apparently obvious until the *accumulation of confirmatory proof* became so strong as to render that attitude of disbelief no longer tenable As a result his work has stood and will continue to stand , in no single instance has Washbourn been forced to contradict or to modify any of the statements or views that he had once put forward. As a teacher and lecturer he has left his mark upon each of the *departments of Guy's* Hospital and its medical school with which he has been successively connected The anatomical, physiological, and bacteriological departments of the school and the wards and electrical department of the hospital have all benefited by his powers of organisation and his keen insight into the requirements and the needs of the present-day medical student He was deservedly popular with his colleagues and equally so with the students, with whom his interest in their sports and amusements created another strong bond of fellowship As a man he was a staunch friend and a strong partisan, and *at the same time* a fair and considerate opponent. In the field of controversy as in social life, he commanded the respect and esteem of all his fellows, whilst in those with whom he was brought in contact in daily life his personal characteristics and utter neglect of self inspired an affectionate regard and love which makes each one look upon his death as causing a heavy personal bereavement. His opinion and advice were constantly being sought by all who knew him and it may be said truthfully that none went empty away: sound practical advice and kindly words of encouragement tiding many a man over some critical period. His death will be most keenly felt, not only amongst those who knew him best, but throughout the entire world of medicine and science. That so brilliant a career and one so full of the brightest promise should have been cut short at the early age of 39 years hardly seems in accordance with the eternal fitness of things, but those who are left behind to mourn that loss can have no higher ideal than the attempt to attain the high standard of personal and intellectual rectitude which he has set.

PROFESSOR ADOLF KUSSMAUL.

OUR Berlin correspondent writes:—Professor Adolf Kussmaul, who died not long ago at Heidelberg, was the oldest and one of the most celebrated clinical teachers of Germany. Although it is now some years since he retired from his official duties on the ground of his advanced age (he was more than 80 years old) he nevertheless continued to work up to the very close of his life through unwillingness to disappoint the numerous applicants for his advice. Professor Kussmaul's career presented some unusual features. His early life has been admirably described by himself in his interesting work, "Jugenderrinnerungen eines Alten Aerztes" ("Memoirs of an Old Physician"), a book valuable for the accounts which it gives of the university and medical life of that day. The son of a country practitioner whose family connexions were of the peasant class he early in life became acquainted with the hardships of country practice but was not thereby deterred from following in his father's steps. While a student at Heidelberg University he published a physiological prize essay, its subject being the Sensibility of the Retina. At that time the importance of pathological anatomy was beginning to be understood by the medical profession and on the completion of his curriculum Kussmaul attended the lectures of Professor von Rokitansky in Vienna and Professor Oppolzer in Prague. On his return home he became a surgeon in the Baden army and when he retired from the service in 1849 he settled as a country practitioner in the little village of Kandern in the Baden highlands. The work in this mountainous district was carried on under considerable difficulties for some years, until in 1854 he contracted spinal meningitis with total paralysis of the lower extremities, the cause of the attack probably being over-exertion. He fortunately recovered although his symptoms were for a time most critical, but he felt himself unequal to the fatigues of country practice. He was now 32 years of age and was, of course, qualified as a practitioner, but he made up his mind to resume medical study and matriculated as a student at Würzburg University with the view of increasing the knowledge of pathological anatomy which he had acquired in Vienna and Prague. Two of his teachers at Würzburg—namely, Professor Virchow and Professor Kölliker—are still alive. A year later he took the degree of M.D. at Würzburg University and in 1856 he returned to Heidelberg where he was recognised as a *privat docent*. In 1857 he was promoted to be extraordinary professor and in 1859 he was appointed ordinary professor at the University of Erlangen. In 1863 he left Erlangen for Freiburg and remained there until 1876, when he was invited to fill the chair of clinical medicine at Strassburg University in succession to Professor von Leyden. His practice as a consultant was very extensive in Freiburg and was increased in Strassburg. During this period he published the results of his scientific researches in a great many books and essays. In 1888 he resigned his appointment and retired to Heidelberg where he spent the remainder of his life and where last winter his eightieth birthday was celebrated with much enthusiasm by members of the university, his professional brethren, many of his patients, and the townspeople in general. The municipality of Heidelberg presented him with the freedom of the city, the Grand Duke of Baden granted him the title of Real Privy Councillor, and many other honours were conferred on him. The wide range of his knowledge enabled him to work in almost every branch of medicine. In general pathology he published essays on the influence of the circulation on the temperature of the ear in rabbits and on the origin of epileptoid convulsions in acute anæmia. Pathological anatomy was represented by his works on congenital anomalies of the uterus and on post-mortem rigidity. His principal works in clinical medicine were "On the Treatment of Dilatation of the Stomach by means of the Stomach-pump" and "On Paracentesis in Pleurisy." His essay "On the Psychology of Newly-born Children" and his well-known treatise "On Disorders of Speech" belong to neurology. Professor Kussmaul was of a kindly and amiable disposition which gained him many friends and has caused his death to be widely regretted.

THOMAS JAMES WOODHOUSE, M.D. LOND., F.R.C.S. ENG.

PUTNEY has recently lost through death a highly esteemed inhabitant in the person of Dr. Thomas James Woodhouse of Amboise, Rusholme-road, Putney. The deceased was well known in the parish and was greatly respected by all who came in contact with him, while to those who were closely associated with him he proved a valued and never-failing friend. He died on June 11th after a short illness extending over only a few days. He commenced his career as a student at St. Thomas's Hospital and in 1865 graduated M.D. of London, having in 1860 obtained the diploma of F.R.C.S. Eng. He bought a practice at Fulham where he lived at Ranelagh Lodge for several years. He was greatly interested in archæological subjects and assisted in the restoration of Fulham Church. In 1864 he wrote a book on the epitaphs within and without Fulham Church and also prepared a paper on the monuments and tombs there. This he read at a meeting of the British Archæological Society of which he was a member. Subsequently Dr. Woodhouse removed to Putney where he continued to live until the time of his death. He held the appointment of medical officer at the Royal Hospital for Incurables, Putney Heath, a position which he retained for 36 years. He retired from the post on Jan. 1st, 1902, when he was the recipient of an illustrated address bearing the following dedication: "Presented to Thomas James Woodhouse from the patients of the Royal Hospital for Incurables, Putney Heath, on his retiring from the institution after 36 years of faithful service." The inmates also presented Dr. Woodhouse with a gold watch as a mark of their appreciation of his talent and kindly disposition.

The first part of the burial office was sung at Holy Trinity Church, West Hill, Putney, on June 17th. The officiating clergy were the Rev. J. A. Webb and the Rev. C. H. Venning (of Gospel Oak). There was a large congregation and amongst those present were Mrs. Lenicke (matron of the hospital), the staff, and 17 patients in chairs. The chief mourners were Mr. Sidney Woodhouse, Mr. and Mrs. Vernon Woodhouse, and Mr. Haward Chaplain. The following gentlemen were present to represent the hospital: Colonel Holland, Mr. John Gay, the medical officer, Mr. Fox, Mr. Bellamy, and Mr. W. D. Newton. The body was then taken to the Putney Cemetery, Barnes Common, for interment, the prayers of committal being said by the Rev. C. H. Venning.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the congregations on June 12th and 17th the following were admitted to medical and surgical degrees:—

Doctor of Medicine.—C. K. Williamson, Trinity; W. B. Winton, Clare; and J. N. Gardiner, Trinity Hall.

Bachelor of Medicine and Bachelor of Surgery.—A. J. Smey, King's; H. V. Pryce, St. John's; H. R. Mayo, Caius; F. W. Hardy and G. H. L. Whale, Jesus; B. L. T. Barnett, St. John's; J. Barnicot, Pembroke; and H. H. Stiff, Caius.

Bachelor of Medicine.—J. L. H. Snell, Caius; H. C. Brown, Emmanuel; G. H. Sedgwick, Sidney Sussex; R. Gordon-Smith, Trinity; B. Spearman and R. Spearman, Caius; and F. L. Shipway, Christ's.

Bachelor of Surgery.—F. Sanger, St. John's; and G. T. Barham and F. G. Bowen, Caius.

Dr. E. Laming Evans, M.A., Trinity, has been awarded the

Raymond Horton-Smith prize for the best M D thesis of the year —Dr W H R Rivers, St. John's, has been reappointed University Lecturer in Physiological and Experimental Psychology —Dr D MacAlister, St John's, has been appointed Assessor to the Regius Professor of Physic

UNIVERSITY OF DUBLIN TRINITY COLLEGE —At examinations held at the School of Physic, Trinity term, the following candidates were successful —

Final Examination Section 4 —Michael J M Auliffe Henry Stokes Herbert Stone Douglas B Thomson, Thomas C A Sweetnam, Harold T Marrable Philip S Stewart Frederick W Bury, James F F Walsh Cecil J Wyatt Thomas King Edwards, George S Walton, and Thomas Ryan

FOREIGN UNIVERSITY INTELLIGENCE —*Basle* Dr Wilhelm His, jun , of Dresden, and formerly of Leipsic, has been offered the chair of Medicine His father, the well known professor of anatomy in Leipsic, was for some years on the staff of the Basle Medical Faculty —*Bordeaux* Dr Le Dantec has been appointed to the chair of Tropical Medicine.—*Gottingen* The Senate has decided to refuse the right of matriculation to female students —*Heidelberg* Dr F Marschall has been recognised as *privat docent* of Hygiene and Dr R. H Weber as *privat docent* of Physiology —*Leipsic* Dr Riecke has now been recognised as *privat docent* of Dermatology —*Odessa* Dr P Borisoff has been appointed Professor of Pharmacology , Dr V Masen, Professor of Midwifery and Gynæcology , Dr M Mikhailoff, Professor of Special Pathology and Therapeutics , and Dr Szapjeshko, Extraordinary Professor of Surgery —*Paris* Professor Fournier, the well known syphilologist, is about to retire as he is in his seventieth year His successor will be Hallopeau.—*Strasburg* Dr A. Stolz has been recognised as *privat docent* of Surgery

ANDERSON'S COLLEGE MEDICAL SCHOOL, GLASGOW —The summer session has just closed. It was curtailed by a few days owing to the general arrangements for the Coronation festivities which unhappily were postponed. The number of students matriculated was much the same as that of previous summer sessions and the work performed in the various departments of the school was highly satisfactory to teachers and students alike

THE HEALTH OF LEICESTER —Dr C K Millard, medical officer of health of the borough of Leicester, in his report for 1901, just issued, says that undoubtedly the most satisfactory feature of the year's statistics is the exceptionally low rate of mortality—viz , 15 71. This is the lowest on record for the borough with the exception of that for the year 1894 During 1901 the number of marriages solemnised was 1825, equal to a marriage-rate of 17 17 per 1000 The number of births registered during the year was 6169 This is 38 less than in the previous year and 50 less than the average of the previous five years , 3132 of the births were males and 3037 were females The birth rate was equal to 29 03 per 1000 of the population The following are the birth rates for the previous five years —1896, 32 0 , 1897, 31 63 , 1898, 30 56 , 1899, 30 61 , 1900, 29 75 , and 1901, 29 03 "It appears, therefore," says Dr Millard, "that owing to the continued decrease in the birth rate and in spite of the increasing population the actual number of children born annually has not only ceased to increase but is actually beginning to decrease. This has already been the case for some years in several of the other great towns—notably, in Derby and Huddersfield " The number of illegitimate births in the borough during 1901 was 210, equal to 3 4 per cent. of the total births The total number of deaths registered during the year was 3373, but only 3338 were of residents of Leicester—1701 males and 1637 females Of these, 1098 were of infants under one year of age, giving an infant death rate of 177 9 per 1000 births. The average for the previous 10 years is 195 4 The infantile mortality, adds Dr Millard, is rightly regarded as an important index of the sanitary condition of a locality Unfortunately, in Leicester the rate is unduly high owing to the heavy mortality caused by diarrhœa, and if the deaths registered as due to diarrhœa and enteritis be excluded the infant mortality for Leicester for last year would have been but 129 Under the heading of zymotic diseases Dr Millard's report contains the following in reference to the 'Leicester system" of dealing with small pox "'The Leicester experiment' has now been tried too long and been attended with too great success for it to be entirely ignored in considering the question of the necessity for compulsory vaccination. At the same time nothing that have seen so far has in any way affected my belief ha vaccination and revaccination, repeated when necessary will confer complete protection against small pox Indeed I regard this as not merely a matter of belief but as on capable of absolute scientific demonstration."

HOSPITAL SATURDAY FUND AT EXETER —At th meeting of the committee of the Exeter Hospital Saturda Fund held on June 24th it was reported that the tota amount collected last year amounted to £711. It wa decided to distribute £633 amongst the different medica charities of Exeter Sept 27th is to be observed a Hospital Saturday this year

THE LATE MR A WADE —Mr Arthur Wad died at his residence, Melbourne, Boscastle, Cornwall, o June 27th, in his eighty second year He received hi medical education at University College Hospital, London taking the diplomas of M R C S Eng in 1843 and L S A. i 1871 The deceased had been for many years in practice a Boscastle, where he was formerly medical officer of health district medical officer, and public vaccinator, but recently h had retired from active work. Mr Wade was a justice o the peace for the county of Cornwall. He was of a genia and kindly manner and was very popular in Boscastle and the surrounding district.

THE AMENITIES OF NATIONS —England's lates ally in the Far East has in many ways convinced th continents of the world that she is rapidly levelling up t the highest standards of national progress and well being, and an instance of the enlightenment of our Japanes allies is afforded us by a well-designed card we hav received from Messrs Z P Maruya and Co of Tokyo Japan, offering their congratulations on the coronation o His Majesty the King and their sincere wishes for the continued prosperity of the British Empire Although the unforeseen happened, none the less the friendly spirit is manifested and is worthy of record We thank our Japanes friends and reciprocate their greetings

SMALL-POX IN CAMBRIDGE —During the recent epidemic of small pox in Cambridge a patient suffering from the hæmorrhagic form of the disease was admitted into th Infectious Diseases Hospital as a case of scarlet fever D E Lloyd Jones of Cambridge thereupon wrote or communicated statements to the public press which reflected serious upon Dr B Anningson, the medical officer of health, an "the medical attendant at the sanatorium " Dr Anningso having proved to Dr Jones that his statements were unfounded, Dr Jones wrote the following letter to the *Cambridge Daily News* of June 23rd The apology, if somewha belated, is at least full

To the Editor the *Cambridge Daily News*

SIR —With regard to the letter that I wrote to your paper o March 7th, 11th, 14th and 21st, I wish to state that the medical office for the borough has since given me ample and satisfactory explanatio upon the matters therein criticised

I should now like to express publicly my regret at having hastily written on inadequate information in the way I did and I am glad t say that it was not in any way whatsoever my intention to throw discredit upon the action and conduct of Dr Anningson

Yours etc
E LLOYD JONES

VACCINATION EXPENDITURE —At the meeting o the Bideford Board of Guardians held on June 24th a discussion took place with regard to the vaccination expenditure. Some of the guardians expressed astonishment that a numbe of persons in good positions and living within a quarter of a mile of the public vaccinator's house should have sent fo him to revaccinate themselves and their servants at their own residences, and they inquired whether voters would not on this account be debarred from voting at the next election Mr Preston Thomas, Local Government Board inspector, thereupon explained that vaccination was not Poor law relief, that it did not entail any disabilities, and that anyone was entitled to demand vaccination at the public expense The public vaccinator, however, was not entitled to go to a house to revaccinate people there unless they had previously sent for him —At the meeting of the Axminster (Devon) Board of Guardians held on June 19th it was reported that the Admiralty had refused to pay for the revaccination of the wives and children of the coastguard at Axmouth.—At the meeting of the Torrington (Devon) Board of Guardians held on June 14th the clerk in answer to inquiries stated that the publication of the names on the vaccination register would probably lead to difficulties and added that any reporter publishing the names might be made answerable for doing so. Eventually the guardians resolved that the consideration of the vaccination register should take place in committee.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

ELECTION OF MEMBERS OF COUNCIL.

THE fourteenth election of Fellows to fill the vacancies in the Council of the College under the new regulations was held at the College, Lincoln s Inn Fields on Thursday July 3rd between 1 30 and 4 30 P M

The result of the voting was as follows —

	Votes	Plumpers
MR H MARSH	415	7
MR. J H MORGAN	393	30
MR. H H. CLUTTON	311	31
MR. C W MANSELL MOULLIN	293	54
MR JORDAN LLOYD	241	9
MR J BLAND-SUTTON	228	14
SIR WILLIAM H BENNETT	205	4
MR. CLINTON T DENT	85	0

Mr. Marsh is therefore, re-elected Mr Morgan Mr Clutton and Mr Mansell Moullin are elected members of the Council

743 Fellows voted 19 personally and 724 through the post 6 proxies arrived too late.

Parliamentary Intelligence

NOTES ON CURRENT TOPICS

Plumbers' Registration Bill.

THIS Bill after having passed through the House of Lords, has been dropped. In the House of Commons it never got beyond the stage of introduction

Proposed Registration of Motor Cars

A Bill has been introduced in the House of Commons by Mr Scott Montagu for the registration of motor cars and for the amendment of the law as to the speed at which these vehicles may run

London Water Bill.

Members of the House of Commons have now before them the report of the Joint Committee on the London Water Bill and in view of the consideration of the measure in committee of the whole House they have prepared a long list of amendments. There is every prospect of the stage being a protracted one.

The Sale of Butterine

Mr Hanbury has undertaken to make several alterations in his Bill with respect to the sale of butterine Generally speaking what the Bill does is to apply to this article the provisions of the Sale of Food and Drugs Acts relating to margarine. It defines butterine as butter to which any substance has been added whereby the amount of water in the butter is increased and to this definition Mr Hanbury proposes to add these words: and any water in excess of the proportion prescribed by the regulations in force for the time being under Section 4 of the Sale of Food and Drugs Act 1899 which shall be found in any butter or butterine sold or exposed or offered for sale shall be deemed to be due to the addition of such substance unless the vendor shall prove that it is due to the ordinary process of butter making" Mr Hanbury also proposes to exclude Irish salt firkin butter from the scope of the legislation

HOUSE OF COMMONS

MONDAY JUNE 23RD

Public Health Arrangements in Hong-Kong

Mr WEIR asked the Secretary of State for the Colonies if he would state whether the provisions contained in Sections 73 to 80 of the Public Health Ordinance, No 13 of 1901 relative to overcrowding in the city of Hong Kong were enforced, and if so, would he say how many persons had been deputed by the Hong Kong Government to enforce this Public Health Ordinance —Mr CHAMBERLAIN replied The answer to the first part of the question is in the affirmative. In answer to the second part I can only say that the total number of the sanitary staff of the colony is about 140.

Famine in India.

Mr LEAMY asked the Secretary of State for India whether in order to make provision against the prolongation of the present famine in India which began in July 1899 he would consider the advisability of inviting Parliament to make an inquiry into the condition of the people affected by the famine and to ascertain whether more effective means could be employed to deal with it and also to ascertain whether it was possible to take better preventive measures against future famine; and whether he had any official information showing what the supply of food in India had been during the present famine —Lord GEORGE HAMILTON replied: The relief given in India to mitigate the distress to which the honourable gentleman refers has during the last two years, partaken very much of the character of Poor law relief such as prevails in this country; and the numbers in India in receipt of such relief in proportion to the population are much less than those at the present moment in Great Britain receiving similar help The most effective means of dealing with drought in India which is the origin of the distress have been exhaustively inquired into and reported on by the recent Famine Commission, and Railway Commissions are dealing separately with the preventive measures which their respective branches of inquiry suggest I do not propose to order further inquiries During the recent famine the supply of food has proved sufficient.

Medical Officers in the Scottish Crofting Counties

On the motion of Mr WEIR there was ordered a return showing the number of medical officers dismissed by parish councils in each crofting county during each of the seven years 1895-1901 the name of the parish council and the cases in which a cause of dismissal was assigned

WEDNESDAY JUNE 25TH

Hospital Accommodation for Belfast

Mr T W RUSSELL asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that in dealing with special hospitals for small-pox patients the Local Government Board insisted upon the buildings being at least a quarter of a mile from any dwelling house that being the striking distance of the contagion upon which the English authorities acted; and whether he was aware that at Purdysburn county Down where the Corporation of the City of Belfast proposed to erect a temporary small pox hospital, there were inhabited houses, a dairy and a national school within the radius as prescribed in England; whether the sanction of the Local Government Board was required or had been given for the erection of this building; and was he aware that the City of Belfast, although a seaport, was without any small pox or isolation hospital.—Mr WYNDHAM replied: The requirement pointed out in the first paragraph is insisted upon by the English Local Government Board only in the case of small pox hospitals provided out of loans sanctioned by it The sanction of the Irish Department is not required unless in the event of an application for a loan If such an application be made the Board will consider the question in all its bearings The board of guardians maintain an isolation hospital in Belfast in which small pox cases are treated

FRIDAY JUNE 27TH

Grocers Licences

During the consideration of the report stage of the Licensing Bill there was much discussion and an important decision on the proposal to place grocers licences under the control of the local justices like public-house licences In the present state of things grocers licences are issued by the Excise authorities. It was decided that existing licence-holders shall not be required to apply to the justices for a licence but that the justices may refuse renewal in a case where they are satisfied that the licensee has sold surreptitiously under such licence, or has assisted in selling or misrepresenting the nature of the goods sold or has in any other way in the opinion of the magistrates been guilty of misconduct in the conduct of such business.

TUESDAY JULY 1ST

The Ventilation of the House of Commons

Mr WYLIE asked the First Commissioner of Works what steps if any had been taken to improve the ventilation and other sanitary arrangements of the House during the last two months.—Mr AKERS DOUGLAS replied that the Select Committee recently appointed to report on the ventilation of the House was carefully considering the question but had not yet finished its investigations. Most of the improvements in the committee rooms &c. for which provision was made in this year s vote had been carried out but the completion of the work had not been practicable while the business of the House had been going on

ROYAL COMMISSION ON ARSENICAL POISONING

THIS Commission held another meeting on Friday June 20th Lord KELVIN presiding

Mr ARTHUR R. LING Fellow of the Institute of Chemistry and Member of the Society of Public Analysts, gave evidence in association with Mr B E. R NEWLANDS Past Vice-President of the Institute of Chemistry He said that in the course of a very large experience with malting fuel they had never met with a sample free from arsenic. To determine arsenic in fuel they had taken advantage of the fact discovered by one of them (Mr Newlands) that when fuel was mixed with a base such a lime or soda and burnt any arsenic it contained was retained with the ash. Their method consisted in burning two portions of the fuel one portion alone and another mixed with an excess of lime or any other convenient base and determining the arsenic in a solution in hydrochloric acid of each of the residues thus obtained by the Marsh Berzelius test. The amount of arsenic found in the residue from the plain fuel represented the fixed arsenic, whilst that found in the residue of the fuel and base was the total arsenic The difference between these two amounts gave the volatile arsenic. This method had, they believed, come into general use and it had been recommended by the Joint Committee of the Society of Chemical Industry and the Society of Public Analysts Welsh anthracite coal was so variable in its composition that it was almost impossible to of anyone who wishes to go out to South Africa for his health, suggesting someone suffering from early phthisis pulmonalis My friends have a vacancy for a gentleman who will have board lodging and laundry free in return for two hours daily tuition of their son a youth aged 17 years in general English knowledge They are loyal Dutch farmers who have suffered severely through the war and are consequently unable to offer any further remuneration than free quarters, &c., in a very comfortable home with fairly liberal table Not knowing of anyone myself to suit their requirements it occurred to me that amongst your readers there might be one who has a patient who would only be too glad to avail himself of such an opportunity If so would he communicate with me when I should be glad to supply any further details I inclose my card

I am Sirs, yours faithfully,

July 1st 1902. M.B

THE LAW FUND

Dr. R Paramore sends us for publication the following letter from the Dowager Lady Jenner widow of the late distinguished President of the Royal College of Physicians of London —

> I enclose a cheque for £5 5s as a contribution to the fund which is being raised to defray Dr Law's costs in the action brought against him by a patient whom he had treated with the greatest attention and kindness I feel sure that my husband if he were living would have willingly subscribed to the fund and would have felt the greatest sympathy for Dr Law

Dr Glover at the meeting held for the purpose of helping Dr Law, referred to the kindness of Sir William Jenner in taking up a case similar to that of Dr Law where a medical man was badly treated He held meetings at his own house and by his influence evoked such practical sympathy that even a larger sum of money was obtained than that required for actual costs The following additional subscriptions have been received by Dr Paramore, 2, Gordon-square, W C Cheques and postal orders should be made payable to the Law Fund" and crossed London and County Bank Holborn —

THREAD WORMS AND APPENDICITIS

To the Editors of The Lancet

Sirs —About a year ago my daughter, aged seven years had vermiform appendix removed in the United States On slitting open the appendix 16 thread worms were found alive in the interior Can any of your readers inform me if these worms would be likely to have caused the appendicitis also, are there many similar cases on record?

I am, Sirs yours faithfully,

July 1st, 1902. Harlesden

THE "Y" FUND

Surgeon General H S Muir begs thankfully to acknowledge additional donations towards the above Fund from Mr G Easte Mrs F Surgeon General W McNamara, C B , Colonel and M Carr Calthrop, I M S , Lieutenant-Colonel C H Beatson, M S Civilian Surgeons (attached to the Royal Army Medical Corps in South Africa) J G Bell, D Munro, F G Sharpe, T H D Hale and J Woodhouse , and the following officers of the Royal A Medical Corps: Lieutenant Colonels G Brazier-Creagh, T W N J Maconachie A T Sloggett, C M G , J Duncan, and A Hart Majors H O Trevor S Butterworth, S Hickson, H C G F Gubbin B Westcott C M G , H T Baylor, F D Elderton T W C H Hamilton, C M G , R C Thacker, and M O Captains A R Morgan K B Barnett, H W K Read, H P Johnson and E E Powell , Lieutenants G H Goddard, J I W Morris, W C Croly , R F Ellery , H F Shea, D L Harding, R B Black G H Usmar and L M Purser , the Medical Officers of General Walter Kitchener's force (through Lieutenant-Colonel Porter) and the Principal Medical Officer and Officers Orange River Colony The fund now amounts to £368 It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly "handing on" to *confrères*) Should any reader of The Lancet desire further particulars with a view to expressing *practical sympathy*, a copy of the letter will be forwarded on application to Surgeon General Muir, 26, Kensington gardens terrace, Hyde Park, London, W

◆

Ind —We have referred our correspondent's question to the Scotch Education Department the secretary to which has replied "The questions involved bear upon the interpretation of the Education Acts in regard to which my lords have no power to give any authoritative decision Such questions must if necessary be decided by a court of law Even with this restriction my lords have only intervened and can only intervene in the matter so far as it has been or may be found to affect the administration of the Education Acts in particular cases They can offer no opinion whatever regarding it as bearing upon claims made by medical officers, as this is entirely outside their province In a similar matter coming under the London School Board the procedure is as follows The duty of a school board is to see that the children attend school If a child is absent the board may demand that the child's parent should show cause for his or her absence If the parent cannot do this by means of a medical or other certificate the board can summon the parent before a magistrate. But a school board has no power to demand a medical certificate for the absence of a child from school The London School Board states on the forms of medical certificates which it supplies (although it has no power to demand such certificates) that it will not be liable for any expense connected with such certificates We do not remember that the point has hitherto been decided by a court of law

Sigma —We do not know any book but one dealing exclusively with the subject although chapters on the subject are found in many especially American, works The book in question is a small pamphlet written by Mr Maurice C Hime, M.A , LL.D , and published by Messrs J & A Churchill

X Y Z —As our correspondent found relief from strychnine under the same conditions some years ago we think that he might very well try it again—combining the use of it with nitro-glycerine if necessary

Communications not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received —*Daily Express (Dublin) Torquay Directory Yorkshire Mercury, Local Government Chronicle, Sanitary Record Derbyshire Courier Surrey Advertiser, Local Government Journal Carpenter and Builder, Rotherham Express, Liverpool Daily Post, Journal of Tropical Medicine Westminster Gazette, Knowledge, Broad Arrow Torquay Times, Midland Express, Army and Navy Gazette Weekly Free Press (Aberdeen), Bristol Mercury, Madras Journal Reading Mercury, Mining Journal, Herefordshire Mercury Daily Telegraph Le Progrès Médical, Scientific American, Literary Digest, Gazzetta degli Ospedali e delle Cliniche, Deutsche Medicinische Wochenschrift, New York Medical Journal, Journal of the American Medical Association*, &c.

ATURDAY (12th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic 0 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the entral London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

EDNESDAY (9th).—DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—5.15 P.M. Demonstration of Cases of Interest.

HURSDAY (10th).—BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Specimens will be shown by Mr. Jessett, Dr. Hodgson, Dr. Purcell, and others. Papers:—Mr. B. Jessett and Dr. H. Hodgson.

RIDAY (11th).—BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION (11, Chandos-street, Cavendish-square, W.).—4 P.M. Cases and Specimens will be shown and Papers read by Mr. L. Brown, Dr. W. Milligan, Dr. Abercrombie, and others.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (7th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. T. Colcott Fox: Clinique. (Skin.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M.: Mr. Beddard: Methods and Significance of Examination of the Blood.

TUESDAY (8th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. S. Taylor: Clinique. (Medical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M.: Dr. Russell: The Examination of the Stomach and its Contents.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M.: Dr. J. Taylor: Anomalous Forms of Tabes Dorsalis.

WEDNESDAY (9th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Mr. J. Berry: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M.: Mr. McAdam Eccles: Surgical Anatomy.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M.: Dr. Acland: Subphrenic Abscess and Pneumothorax.

THURSDAY (10th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Mr. Hutchinson: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M.: Mr. Keetley: Acute Intestinal Obstruction.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M.: Dr. Poynton: Simple and Malignant Endocarditis in Children.

CHARING CROSS HOSPITAL.—4 P.M.: Dr. M. Davidson: X Ray Demonstration. (Post Graduate Course.)

FRIDAY (11th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Mr. T. Collins: Clinique. (Eye.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M.: Mr. Baldwin: Treatment of Injuries.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1902, which was completed with the issue of June 28th, and the Title-page to the Volume, are given in this number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1902 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2*s.*; by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

Five Clinical Lectures

ON

THE CAUSATION AND PREVENTION OF PHTHISIS.[1]

By BYROM BRAMWELL, M D, F R.C P, F R.S EDIN,
PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY &c

LECTURE II [2]

GENTLEMEN —If we take the preliminary facts which I brought before you in my last lecture as the premisses we must conclude (1) that phthisis is an infectious and communicable disease dangerous to the public health (the same statement, of course, applies to all tuberculous affections in which the tubercle bacillus or its spores are given off from the bodies of affected persons, either in the sputum, in the fæcal discharge, in the urine, in the discharges from diseased bones, joints, &c.[3]), and (2) that phthisis and all other forms of tuberculous disease are preventable affections.

Now whether an individual who has been exposed to infection will contract a contagious or infectious disease or not depends upon two main factors—viz. (1) the intensity of the poison, and (2) the resisting power or susceptibility *of the individual.*

The intensity of the poison depends upon (*a*) the dose, whether large or small, and in this connexion it is important to remember that the number of tubercle bacilli which the sputum of phthisis contains varies in different cases of phthisis and at different stages of the same case (*b*) the source of infection and the channel through which the poison is introduced into the system (whether in the form of dried sputum inhaled and introduced into the respiratory or gastro-intestinal tracts, in the form of tuberculous milk introduced into the gastro-intestinal tract, or by inoculation &c.), and (*c*) the virulence of the poison, germ poisons varying in their intensity from time to time—i e. under different circumstances.

The resisting power of the individual depends upon (*a*) his inherent or constitutional peculiarities, his vital resistance" as it has been termed, some persons being more susceptible to certain poisons than others, (*b*) his condition of health at the time when the virus is introduced into his system and especially in the case of phthisis, (*c*) the condition of the tissues and organs with which the tubercle bacillus or its spores are first brought into contact. In other words, the resisting power of the tissues varies in different families and in different individuals, and the resisting power of the individual may be temporarily modified (lowered or increased) in accordance with his condition of health and in the case of some of the contagious and infectious diseases—and probably this applies with special force in the case of phthisis—in accordance with the condition of the tissues with which the virus happens to come in contact when it is first introduced into the system.

But although phthisis—limiting the argument to the more important form of tuberculous disease so far as the risk of infection and contagion *from* one human being to another human being is concerned—must, under certain circumstances be regarded as an infectious and communicable affection and although every human being is probably under certain circumstances (provided, for example, that a large dose of the poison or a dose of very virulent tubercle bacilli is introduced into the system or provided that the resisting power of the organism as a whole, or of the individual tissues with which the tubercle bacillus first comes into contact, in particular is for some reason or another lowered or diminished) liable to be affected with tubercle, phthisis differs very materially from most of the other contagious and infectious diseases in this most important particular that it is only very slightly infectious and communicable. In other words, the risk which a perfectly healthy person, whose sanitary surroundings are satisfactory, runs of contracting phthisis or other forms of tuberculous disease from being in contact with a person affected with phthisis appears to be very slight. This is shown by the fact that a healthy wife seems comparatively rarely to contract the disease from a phthisical husband whom she nurses all through his illness, and *vice versâ.* After the discovery of the tubercle bacillus by Koch the British Medical Association issued (on Jan 6th, 1883) a circular to all of its members with the object of trying to determine the opinion of the profession with regard to the communicability of phthisis. That circular was as follows —

> Have you observed any case or cases in which pulmonary phthisis appeared to be communicated from one person to another?
>
> Please answer Yes" or No"
>
> If more than one case observed say how many
>
> In the event of your having observed any case or cases the committee will be further obliged if you will give any brief particulars you may think worthy of record. In doing so the following points should be noted:—
>
> 1. The date when the observation was made.
> 2. The relationship, if any between the individuals concerned.
> 3. The presence of family predisposition to the disease. It should be particularly noted whether the disease had occurred in the parents, grandparents, and other relatives or only in the brothers or sisters of the person to whom the disease was communicated.

In response to this circular 1078 replies were received.

> A great number of these returns (673) were simple negatives containing only the word No meaning that no case had been observed by the member making the return but without any expression of opinion These returns admitting of no further analysis, have been set aside. The remaining answers contained observations of some kind and these have been classified as follows:—Class 1 affirmative observers 281; Class 2, doubtful observers, 39; and Class 3 negative observers 105. Out *of the 1078 members of the Association who have returned answers* to the questions issued on this subject at least 281 believe they have seen cases of phthisis which have originated in communication from one person to another about 39 more have seen cases which have made them doubtful whether phthisis may not be so communicated; while 105 offered facts and arguments which seemed to them to negative such a view 158 of the affirmative returns refer exclusively to cases observed between husband and wife. Communication between husband and wife is mentioned together with other cases, in 34 of the remaining returns So that 192 observers report cases of supposed communication of phthisis occurring between husband and wife
>
> Of the cases in which it is distinctly specified which partner conveyed it to the other in 119 it is stated that the disease was transmitted *from* husband *to* wife; in 69 *from* wife *to* husband. It is distinctly stated in 130 of these cases that there existed *no family predisposition* to phthisis in the partner to whom it was supposed to be conveyed

In summarising these returns the Collective Investigation Committee of the British Medical Association states —

> One fact these returns seem to establish beyond any question and that is, that if phthisis is a communicable disease it is so only under circumstances and conditions of extremely close personal intimacy such as persons sharing the same bed or the same room or shut up together in close ill ventilated apartments.[4]

In his great work on ‘The Diseases of the Respiratory Organs the late Dr Wilson Fox summarises his conclusions as to the frequency with which phthisis is contracted by a husband from a wife and *vice versâ* in the following statement —

> I have already attempted to show that the large majority of the cases of husband and wife which form the greater proportion of all the returns (63 per cent. Coll. Inv., 87 per cent. Clay) are either not more in number than can be explained by the natural prevalence of phthisis apart from contagion or may be due in both partners to their exposure to the same cause [5]

Although I am personally disposed to think that the percentage of cases in which a wife contracts phthisis from a phthisical husband and *vice versâ* is probably considerably greater than the results of the Collective Investigation Committee of the British Medical Association show and certainly very much greater than Dr Wilson Fox allows, we may take it that a healthy wife more especially when her sanitary surroundings are good, comparatively rarely contracts phthisis from a tuberculous husband and *vice versâ.* Now the number of wives unaffected with phthisis who nurse their husbands who are affected with phthisis all through the course of the disease is very great and the number of persons unaffected with phthisis who live in the closest contact with their wives who are affected with phthisis is also very great So far as I see there is only one conclusion to be drawn from these facts—the conclusion which has just been stated—viz, that although every case of phthisis is due to the introduction into the body of the tubercle bacillus the disease is only slightly infectious in the case of perfectly healthy persons and that the risk which a perfectly healthy person whose sanitary surroundings are quite satisfactory runs of contracting phthisis from being in contact with a patient affected with phthisis is very much less than one might *a priori* suppose.

---

[1] Lectures I., II and III were delivered in abstract at the Edinburgh Royal Infirmary in March, 1899; Lectures IV and V were delivered in the form of an address to the Fifeshire Medical Association at Kirkcaldy on May 5th, 1899

[2] Lecture I was published in THE LANCET of July 5th, 1902, p 6

[3] In some tuberculous affections (as, for example in tuberculous meningitis and in *some cases of acute tuberculosis*) in which there is no expectoration, no diarrhœa, no affection of the genito-urinary tract, and no discharge from diseased bones and joints, the tubercle bacillus is not given off from the bodies of the affected persons. Such forms and cases of tuberculous disease are not, therefore, so long as there is no discharge of tubercle bacilli or their spores from the bodies of the patients, infectious and communicable though they may at any period of their course, become so

[4] Report of the Collective Investigation Committee of the British Medical Association, July 1883

[5] Diseases of the Lungs, p. 603.

Further, this opinion seems to be supported by the fact that although it is probable from the extreme prevalence of phthisis in this country, more especially in our towns, that almost every practitioner of medicine must over and over again have inhaled the tubercle bacillus or its spores, yet comparatively few practitioners of medicine contract phthisis. The fact to which Sir Hugh Beevor draws attention, that the sparse populations of country districts die from phthisis in as large proportion as the population of towns provided only that the factor of overcrowding is eliminated shows how widely diffused the poison (the tubercle bacillus and its spores) must be. In other words, the susceptibility of the individual who is exposed to infection is a most important factor in determining whether he will become infected or not From a practical point of view—viz., whether the individual will actually become affected with phthisis or not —the mere fact of exposure to infection (i e, the introduction of the bacillus into the body), though essential for the production of the disease, seems to be of less importance than susceptibility of the individual who is exposed to infection Or, as Sir Hugh Beevor puts it "When death returns and local agencies inducing susceptibility are considered together they confirm the common opinion—avoiding susceptibility one avoids infection "[6] Personally I am disposed to think that, speaking generally, a *perfectly healthy* person who inhales the tubercle bacillus runs very little risk of contracting phthisis, and in holding this opinion I am quite in accord with many of the very highest authorities on the subject. Thus Dr Wilson Fox[7] states "There are few writers who have not admitted the possibility of some contagion but I venture to think that the evidence as it stands shows that, even if this possibility has an authentic foundation, the extent and degree to which contagion ordinarily extends is singularly small." Dr J K. Fowler[8] states "Now it may be at once admitted that, having regard to the wide prevalence of the disease, the number of cases in which it has been proved to have been directly transmitted from one human being to another is infinitesimal. The possibility is generally admitted, the frequency of its occurrence is a much disputed question" Dr J Niven[9] states "Tuberculosis is a disease not readily or easily acquired, and the onset of phthisis marks either exposure to intense infection or else some profound weakness" And again "It is universally admitted that although tuberculosis is an infectious disease it is generally, more than any other infectious disease, dependent on assisting causes for its propagation." In short, it would appear that for the production of primary phthisis in the human individual not only is the introduction of the poison into the body—usually the lung or some part of the respiratory tract—necessary, but that, in most cases at all events, the lung or some part of the respiratory tract must be in an abnormal or diseased condition or the resisting power of the individual lessened (either as the result of inherited or acquired weakness), in other words, a suitable nidus must (usually) be present (generally in some part of the respiratory apparatus) to allow the tubercle bacillus or its spores, which have (usually) been inhaled either to take root and develop or to be conveyed to the glandular structures in the neighbourhood.

I have long considered it probable that in many cases in which tuberculous disease is developed in the human subject the tubercle bacilli or their spores which happen to lodge upon an abraded or unhealthy (or perhaps even a healthy) surface, do not produce local disease at the point where they fall but are either (*a*) absorbed and conveyed by the lymphatic vessels to the adjacent lymphatic glands where they lodge and subsequently develop, or (*b*) are carried by the blood vessels or lymphatic glands to more distant tissues and organs—i e, without producing any local (tuberculous) disease in the lymphatic glands in immediate connexion with the surface on which they lodge It is extremely difficult to explain in any other way the development of tuberculous disease in the bones, joints, membranes of the brain, &c, in those cases in which careful post-mortem examination fails to detect any other tuberculous lesions or caseous foci in the body—cases in which, in other words, the tuberculous disease in the bones, joints, membranes of the brain, cerebellum, or other tissues appears to be *primary* Absorption from the tonsil and throat, or from the intestinal and respiratory mucous surfaces, is in all probability an important source of tuberculous disease of the cervical, mesenteric, and bronchial glands, without, be it observed, any local tuberculous disease in the tonsil, intestine, lungs, or bronchi But I doubt whether tubercle bacilli which lodge on an absolutely healthy tonsil or an absolutely healthy intestinal, bronchial, or respiratory mucous membrane have any great tendency to produce local tuberculous disease in the part with which they come in contact—granting, of course, that the resisting power of the tissues is normal Further, it is perhaps doubtful—though on this point one must necessarily speak with hesitation—whether tubercle bacilli are absorbed from the healthy mucous surface of the tonsil, intestine, or bronchi, though it is possible, of course, that such may be the case If, however, the tubercle bacilli are, in consequence of an abraded or unhealthy condition of the mucous surface, absorbed and carried to the lymphatic glands in the neighbourhood, it is, I think, highly probable that they will produce (though I do not think that they will necessarily do so in all cases) local tuberculous disease in the lymphatic gland, even in the absence of local disease of the lymphatic structures, more especially perhaps, in persons of a scrofulous or tuberculous tendency—i e, in persons in whom, either as the result of inheritance or other cause, the "vital resistance" is below the normal, or who are unduly susceptible to the irritation of the tubercle bacillus This point, however, is difficult to prove, for it must be remembered that the mere fact that there is absorption from an abraded or unhealthy mucous surface implies that irritating particles other than the tubercle bacilli are conveyed (as well as the tubercle bacilli) to the lymphatic gland, and consequently that, as a result of the absorption of such irritating particles, the lymphatic gland in which the tubercle bacilli lodge may be irritated and inflamed and may in consequence of such irritation be transformed into a suitable nidus for the development and growth of the tubercle bacillus. Provided that the nasal, pharyngeal, and respiratory mucous membranes (tonsils, larynx, trachea, bronchi, and especially minute bronchi and terminal air cells &c) are in an absolutely healthy condition there seems to be little risk (at least, this is my opinion) of the production of phthisis from inhalation of the tubercle bacillus or its spores Under such circumstances the seed falls on barren ground and does not take root and germinate and develop

This supposition—which is of the greatest practical importance—is, I think, very strongly supported by the fact that it is only in a certain proportion of cases of phthisis that the larynx and intestine become affected. In almost all cases of phthisis multitudes of tubercle bacilli pass over and lodge on the laryngeal mucous membrane in the course of 24 hours and in most cases of phthisis the disease continues for many months or even years. Now if the mere lodgment of the tubercle bacilli on the mucous membrane were sufficient to produce phthisis—in persons, be it observed, who are susceptible to tuberculosis as is proved by the fact that they are actually affected with the disease—the larynx ought to become affected in every case of phthisis For the same reason in almost every case of phthisis the intestine ought to become affected with tubercle, for it can hardly be doubted that in almost every case of phthisis some of the sputum is swallowed, and consequently that in almost every case of phthisis multitudes of tubercle bacilli must come in contact with the intestinal mucous membrane. But as a matter of fact it is only in a certain proportion of cases of phthisis that the intestinal tract becomes affected with tubercle.

These facts, then, would seem to show that the mere introduction into the respiratory apparatus or gastro-intestinal tract of the tubercle bacillus is not usually of itself sufficient to produce phthisis or tuberculous ulceration of the intestine, in other words, that tubercle bacilli which lodge on a perfectly healthy mucous membrane do not usually grow and develop and produce tubercle. In short, it would appear that the mere introduction of the seed (the tubercle bacillus or its spores) is usually not of itself sufficient to produce phthisis, but that a second factor a suitable condition of the soil—a suitable nidus—for the growth and development of the seed is generally required for the production of phthisis. It is necessary therefore, to consider in the next place the conditions which produce or which favour the production of this suitable nidus

Diseases of the Lungs p 306.

[9] Manchester Medical Chronicle vol vii. 1897 pp 2 and 10

The influence of heredity —Of late years there has undoubtedly been a tendency to under estimate the importance of hereditary influence as a predisposing cause of phthisis. Before the discovery of the tubercle bacillus hereditary influence was thought to be the essential the most important cause, the direct cause of the disease. After the discovery of the tubercle bacillus and the recognition of the fact that tuberculous disease is always due to the introduction into the body of the tubercle bacillus and is, practically speaking never otherwise developed, the part which heredity plays in the causation of phthisis was rightly thought to be much less important, and was indeed by some entirely ignored.

That there is in many families a hereditary tendency to phthisis and other forms of tuberculous disease cannot, I think, be denied The fact that insurance offices load persons whose parents or near relatives have died from phthisis shows the importance which they and their medical officers, as the result of their experience, attach to heredity as a cause of phthisis At the same time it must be remembered that in many cases in which phthisis or other forms of tuberculous disease appear to be inherited it is not necessary to assume any hereditary predisposition in order to explain the occurrence of several cases of the disease amongst members of the same family The children of a phthisical parent may, for example, be infected by the sputum of the diseased parent , the house in which the family live may be the source of infection (i e., both the parent and the child may be infected from a common source) the circumstances and surroundings of the family quite apart from any inherited tendency may predispose to the production of the disease. Still allowing for these sources of fallacy it must, I think, be admitted that hereditary predisposition in many instances plays an important part in the production of phthisis. It cannot, I think, be gainsaid that in some families, quite apart from all other predisposing causes, there is a greater tendency to be affected with phthisis than in other families. I take it for granted that the weight of medical opinion is strongly in favour of this view

But although phthisis is apt to run in families and to break out again and again in succeeding generations it must be remembered that the disease is not, except in very rare instances, directly passed down from parent to child—phthisis is not directly inherited. Exactly the same statement applies to bovine tuberculosis. It has been shown that calves born of tuberculous cows are only in very exceptional instances affected with tubercle at the time of birth. Thus of 54 427 calves slaughtered in Leipsic during the year 1895 only 107 or 0 18 per cent. were tuberculous while of 9303 cows 4048, or 43·51 per cent. were tuberculous.[10] It is very rare for a child, say of a phthisical mother to be born with tubercle or to manifest tubercle soon after birth. At birth the children of tuberculous parents are usually quite healthy Any tuberculous affection which they subsequently manifest (tuberculous meningitis in infancy or early childhood scrofulous glands in the abdomen or neck in later childhood phthisis in youth and adult life, to give examples) is in the vast majority of cases the result of the introduction of the tubercle bacillus from without and is not the result of the direct passage of the tubercle bacillus or its spores from the parents or ancestors. Baumgarten indeed has advanced the view that the tubercle bacillus or its spores may remain latent in the tissues for long periods of time. He has suggested that phthisis manifested in adult life may in this way be the result of direct transmission from a phthisical parent But, so far as I know this opinion is entirely theoretical and is not based upon any definite or well authenticated facts. Further it seems directly controverted by the fact that if calves born of tuberculous cows are fed on non tuberculous milk and are kept in good sanitary conditions as regards ventilation &c., they do not become tuberculous Persons who come of tuberculous families and who themselves manifest active tubercle (in other words, persons who are popularly said to inherit tubercle) do not inherit tubercle but merely a *tendency to tubercle* They inherit a certain condition of tissues (of constitution as it is popularly termed) which in many cases seems to be a certain condition of chest conformation or perhaps a certain vulnerability of tissue, as it may be termed, which predisposes them to be more readily affected by the tubercle bacillus than other persons who come of a healthy stock—i.e who do not inherit a tendency to tubercle

The exact manner in which heredity predisposes to the production of tubercle has not been definitely determined. Two explanations may be given viz —

1. That in persons who inherit a tendency to phthisis the natural resisting power of the tissues (the vital resistance) is so feeble that the tubercle bacilli or spores when introduced into the respiratory tract are able to take root and to develop—while there is, as I have already pointed out, good reason to suppose that it is not usually able to do or not likely to do in the case of ordinarily healthy persons—i.e. persons who do not inherit a tendency to phthisis. This view supposes that the mere implantation, so to speak, of the tubercle bacillus on the unabraded and healthy surface of the respiratory apparatus of a person who inherits a tendency to phthisis and tuberculous disease is sufficient to produce phthisis in other words, in persons who inherit a strong tendency to phthisis and other forms of tuberculous disease the respiratory mucous membrane, even when unabraded and healthy is, in consequence of its low resisting power a suitable nidus for the development and growth of the tubercle bacillus But though this view may at first sight appear to be plausible, and though it is certainly difficult to disprove, it seems to be contradicted by the facts (*a*) That it is only in a relatively small proportion of cases of phthisis that the larynx and the intestine become affected. In other words, even in persons who are suffering from phthisis—i.e. in persons in whom the capability to be affected with tubercle is demonstrated by the fact that they are actually suffering from the disease—the constant passage of innumerable tubercle bacilli over the laryngeal and intestinal mucous membranes—parts, be it remembered which are a frequent and favourite seat of tubercle—does not produce local tuberculous lesions. Now if mere vulnerability of tissue—if mere diminished resisting power of the otherwise healthy tissues with which the tubercle bacillus is brought into contact—is the manner in which heredity predisposes to phthisis, the larynx and intestine as has been already pointed out, ought in all cases of phthisis, or at all events in a very large proportion of cases to become tuberculous—i.e., infected with local tubercle. (*b*) That many persons who judging from their family history inherit a strong tendency to phthisis and tuberculous disease never themselves actively manifest any tuberculous affection It is not uncommon for example, to find several members of a family successively dying from phthisis and several others exposed to exactly the same conditions, escaping It may of course be said that in the case of the members who escaped the tubercle bacillus was never introduced into the system. But this explanation is in my opinion a most unlikely one Consequently it seems to me that something more than mere hereditary predisposition is *usually* required in order that the tubercle bacillus after it has been introduced into the system, may take root and develop.

2. A second view which in my opinion is more probable, supposes that a person who inherits a tendency to phthisis inherits either (*a*) a peculiarity of chest conformation or some peculiarity of the breathing apparatus (which probably consists of defective respiratory capacity entailing insufficient air change and a tendency to stagnation both of air and of secretions in the terminal air cells and minute bronchi) or (*b*) a peculiar vulnerability of the lung (respiratory) tissue both of which (*a* and *b*) predispose to the production of an unhealthy diseased or catarrhal condition of the terminal air cells, the minute bronchi, and it may be in the laryngeal or bronchial mucous membrane, and that these unhealthy conditions of the respiratory tract form a suitable nidus for the development of the tubercle bacillus

If this view be correct it follows that all conditions which predispose to the production in the lung of those alterations which form a suitable nidus for the development of the tubercle bacillus must be regarded as predisposing causes of phthisis but without the introduction of the tubercle bacillus such conditions are not of themselves capable of producing phthisis. And since, if this view is correct, an hereditary tendency to phthisis chiefly consists in an hereditary tendency to favour the production of those conditions of the respiratory tract (lung, &c.) which form a suitable nidus for the lodgment, development, and growth of the tubercle bacillus, persons who inherit a tendency to phthisis should take special care to guard themselves against bronchial colds, the inhalation of dust particles, against everything, in short, which is liable to produce an unhealthy or catarrhal condition of the minute bronchi and air cells, for in them such abnormal conditions of the respiratory tract are not only (because of their inherited peculiarities, chest conformation, &c) more easily established, but if produced are (in consequence of the fact that their vital resistance against tubercle is feeble) more dangerous (more likely to be followed by the production of phthisis) than in persons who do not inherit a tendency to phthisis

---

[10] Report of Royal Commission, 1898 p 345.

It must, however, be admitted that this explanation is not altogether satisfactory, for it must be allowed that the mere presence of an unhealthy condition of the respiratory tract (a catarrhal condition of the air cells or minute bronchi) does not necessarily of itself (*per se*) always afford a suitable nidus for the development and growth of the tubercle bacillus Children, as has already been pointed out, are comparatively rarely affected with primary phthisis, but catarrhal conditions in the lung and minute bronchi are very common in children. Hence, in order to explain the rarity of primary phthisis in the child as compared with its frequency in the adult, it must be granted that, in addition to a catarrhal condition of the minute bronchi or air cells of the lung, a peculiar susceptibility of the lung tissue to be affected by the tubercle bacillus (in other words, a diminished vital resistance, which is much more frequently present in the lung of the adult than of the child) is necessary

But, further, it is, I think, not unreasonable to suppose—though this is by no means admitted by many authorities—that in those persons who inherit a strong tendency to phthisis the tubercle bacillus, after it has been introduced into the respiratory passages and after it has (in consequence of the presence of a suitable nidus to the production of which the hereditary tendency to the disease predisposes) taken root and begun to develop, does luxuriate and grow more actively and energetically than it does in the lung tissues of persons who do not inherit a tendency to phthisis. In other words, it is reasonable, I think, to suppose that in persons who inherit a tendency to phthisis, the vital resistance of the tissues against tubercle both of the lung tissues and of the tissues of the body as a whole, is less active and potent than in persons who do not inherit such a tendency

We may say, then, that for the production of phthisis (I am speaking of *primary* tuberculous disease of the lungs) three factors are *usually* necessary, viz 1. The introduction (either directly into some part of the respiratory passages or indirectly into the lung tissues through, for example, the gastro-intestinal tract) of the tubercle bacillus or its spores. This is essential. 2. The presence in the respiratory tract of a suitable nidus for the development and growth of the tubercle bacillus or its spores. It is probable, I think, that this is usually necessary, unless the dose of the poison be very large. 3. Defective vital resistance, in other words inability of the tissues, more especially of the respiratory tissues with which the tubercle bacillus and its spores first come in contact, to resist the development of the tubercle bacillus or its spores, after they have been implanted in the suitable nidus (usually an abraded, unhealthy, or catarrhal condition of some part of the respiratory tract) The resisting power of the tissues against the invasion of the tubercle bacillus—the vital resistance—varies, as we have seen in different individuals (being probably greater, for example, in persons who do not than in others who do inherit a *strong* tendency to phthisis) and in the same individual at different times, in accordance with age, condition of health, &c.

Now if these propositions are well founded the main points to which attention must be directed in order to prevent the development of phthisis in the individual are as follows —1 To prevent the introduction of the tubercle bacillus or its spores into the body and, in the case of phthisis especially, into the respiratory tract. 2 To prevent the production or development in the respiratory tract of the local conditions which form a suitable nidus for the development of the tubercle bacillus (unhealthy condition, abraded surface, retention of secretions &c.) 3. To raise the resisting power of the tissues as a whole, and of the respiratory tissues in particular, so that they may be able to destroy and to evacuate the tubercle bacillus after it has been introduced and lodged in the suitable nidus (an abraded or unhealthy part of the respiratory tract)

ON THE

ACETONE SERIES OF PRODUCTS IN CONNEXION WITH DIABETIC COMA

By F W PAVY, M.D Lond, LL D Glasg, F R S,

CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

In an article on Differentiation in Diabetes, published in The Lancet in 1900,[1] I referred to the classification of diabetes into the "alimentary" and "composite" types In the "alimentary" type the error consists purely and simply of the mal assimilation of the food carbohydrate, and, as a consequence, the elimination of dextrose in the urine. In this elimination of sugar we have the full extent of what is wrong in the urine In the "composite" type, on the other hand, an additional faulty condition of urine exists Besides the presence of dextrose there is also a group of products met with derived from a retrograde tissue metamorphosis. The term "grave" has been applied to this form of diabetes, but, as I pointed out in the article to which I have referred, this term, from the sinister idea which it conveys, is not free from objection. In the term "composite," however, we have no such sinister idea conveyed and it at the same time faithfully represents the condition existing, for we have to deal not only with the issue of mal-assimilation of food carbohydrate but likewise with a conjoined occurrence of an abnormal tissue metabolism

In alimentary diabetes the fault consists of the carbohydrate of our food not being properly assimilated and thence being permitted to reach the general circulation as sugar which subsequently runs off as waste material with the urine carrying with it unutilised energy The ill-effects arising from this condition fall under two heads. There is in the first place the effect due to the loss of food material in an unused state, and in the next there is the injury inflicted by the pernicious action of the sugar in abnormal transit through the system Such sugar virtually acts as a toxic agent and in proportion to the extent to which it exists, of which the amount escaping with the urine is a measure, so, looked at generally, is the extent of harm produced. Purely from this abnormal presence of sugar in the system a great many definite ills take origin They stand distinctly attributable to the effect of the sugar, and are escaped from, or relieved, by the adoption of the appropriate treatment for keeping the system free from abnormality in relation to the presence of sugar Besides the production of such specific troubles as boils and carbuncles, gangrene of the toes, perforating ulcer, phthisis, neuritis, kidney degeneration, cataract, and some others, the toxic influence of the sugar tells obnoxiously upon nutrition and saps the general power, and to be able, as can be done in the "alimentary" form of diabetes, to check the passage of sugar through the system and to avert these results deserves to be regarded as a matter of no small importance.

Building up and breaking-down operations are constantly going on in living matter and it is to a defect on the side of the former that "alimentary" diabetes is due. Constructive metabolism is at fault and the carbohydrate of food, instead of being placed in a proper position by protoplasmic agency for proceeding to utilisation, remains in the form of free sugar which, reaching the general circulation and thence the kidney, flows off with the urine in the same manner as anything else of a diffusible nature. Modern views differ from those entertained a short time back regarding the mode of utilisation of carbohydrate matter Instead of, as was formerly thought, being disposed of by oxidation in a non-living state it is now considered that it is as a constituent of living matter that it undergoes oxidation. The seat of the chemistry of life is within living protoplasm and the non living principles become incorporated into living matter preparatory to utilisation. Food material is in the first instance broken up into simple principles and these by the agency of the living matter belonging to the alimentary canal with which they come in contact become appropriated and built up into living protoplasm which yields the source from which the tissues derive their nutrient material Entering thus in the form of proteid into the system our food carbohydrate is protected through the largeness of the molecule within which it is contained from escaping into the urine during its transit through the kidney as happens when sugar in a free form is allowed to reach the general circulation

---

[1] The Lancet, June 16th (p 1706), 23rd (p 1787), and 30th (p 1863), 1900

This view of the action of protoplasm in appropriating carbohydrate by synthesising it into proteid was the outcome of the recognition in the course of my investigations that carbohydrate was susceptible of being cleaved off from proteid by chemical means. The subject was fully entered into in my *Physiology of the Carbohydrates*, published in 1894 We were previously faced with the difficulty of seeing how sugar reached its seat of utilisation in the tissues without its transit through the circulation being revealed by passage into the urine. With carbohydrate incorporated into proteid and conveyed in this form the difficulty immediately disappears.

I have entered into these particulars regarding 'alimentary" diabetes and the metabolism of carbohydrate as a preparatory step to the consideration of the subject to be specially dealt with *Faulty metabolism is at the foundation* of the whole matter In alimentary diabetes the fault lies with the upward line of metabolism or that which is concerned in placing food carbohydrate in a right position for passing to utilisation. In the composite" form of diabetes wrongness of descending metabolism occurs in addition to the wrongness of the other and the wrongness of descent is attended with the associated production of sugar and of the acetone series of products. With such a state of things existing a formidable condition is presented inasmuch as waste is occurring in all directions. There is the loss of sugar from unassimilated carbohydrate and there is also the loss of sugar and of the above-named associated products derived from the wrong tissue breaking down. All are carrying with them in their exit from the body unutilised energy

I have said that in the abnormal destructive metabolism or tissue disintegration occurring in diabetes there is a liberation of sugar on the one hand and of the acetone series of products on the other The two processes ordinarily occur concurrently but they nevertheless must be regarded as distinct. It has long been noticed that the elimination of nitrogen runs with that of sugar and that they bear a definite relation to each other In the starving animal rendered diabetic by ablation of the pancreas or by the agency of phloridzin, after time has been allowed for all the free carbohydrate of the body to disappear the eliminated sugar is derived solely from tissue disintegration. In this tissue disintegration the nitrogen of the proteid is also set free and appears in the urine as ammonia or as urea. As proteid contains a definite amount of nitrogen the quantity of nitrogen eliminated gives a measure of the proteid destruction occurring

Starting upon these premises the relation which the eliminated sugar bears to the eliminated nitrogen supplies the means of calculating the amount of sugar issuing from the disintegrated proteid. Close attention has been given to the matter and a large amount of work performed by different experimentalists with a fairly accordant result, from which it is estimated that as much as nearly 60 per cent. of the disintegrated proteid may come off as sugar That such an amount of sugar can be derived from the *proteid molecule* constitutes a point possessing a most significant meaning It gives support to the view that has been referred to bearing on the passage of food carbohydrate by the synthesising action of protoplasm, into proteid and at the same time suggests that this mode of application of carbohydrate is carried out upon a scale that gives it a position of great importance. Looked at from a further point of view the extensive liberation of sugar from proteid that is susceptible of being induced gives us an idea of the vast store of locked up carbohydrate that exists in the system in a suitable state for application, under normal conditions of metabolism, to the production of energy

The other result of the abnormal katabolism or downward metabolism that may occur in connexion with diabetes is the generation of the acetone series of products consisting of β-oxybutyric acid, diacetic or aceto-acetic acid, and acetone These products form a chain of principles representing successive steps of degradation by oxidation. Beginning with β-oxybutyric acid, the formula for which is $CH_3.CH(OH).CH_2.COOH$, oxidation of the CH(OH) group into CO gives diacetic acid with the formula $CH_3.CO.CH_2.COOH$ which is changed into acetone, $CH_3.CO.CH_3$, by substituting CH_3 for the two end groups $CH_2.COOH$. In these bodies, as with the carbohydrates, we have non nitrogenous principles to deal with but nothing of the nature of alliance between them exists Their kindred connexion is with the fatty series. With the exception of acetone of which a slight amount may be present they are foreign to normal urine. The abnormality therefore, with regard to these bodies is in the presence of the oxybutyric and diacetic acids It has been shown that they represent successive stages of degradation by oxidation and their order of appearance in the urine is from the lowest to the highest form. As mentioned acetone may be discoverable when no deviation from the normal state is apparent. If diacetic acid is present acetone is also so but not necessarily oxybutyric acid. When oxybutyric acid however is present the presence of the other two may be looked for as a consecutive event These principles may be made to appear in the urine of healthy subjects as a result of their ingestion in sufficient quantity and the same order it is stated has been observed to occur For instance after the ingestion of diacetic acid acetone may *be found and after the ingestion of oxybutyric acid diacetic* acid and acetone and even oxybutyric acid itself if the quantity taken has exceeded the limits of the capacity of the system to dispose of it.

For the recognition of acetone in urine Legal's nitroprusside test is the most suitable for clinical purposes. Into a few cubic centimetres of urine a small fragment of sodium nitroprusside is dropped and a little caustic soda is added. A cherry red colour is produced which soon fades. If now an excess of acetic acid be added a carmine-red becomes *developed should acetone be present.*

Diacetic acid is recognised by the port-wine colour which it gives with a solution of ferric chloride On adding ferric chloride solution (B P) to the urine a white precipitate of ferric phosphate is first thrown down This may be removed by filtration and the filtrate then further treated with more ferric chloride. For expedition however it is usual to go on adding ferric chloride till the precipitate of ferric phosphate is dissolved when the diacetic acid reaction is perceptible if any diacetic acid is present. It is necessary to bear in mind that somewhat similar colour reactions are given by the urine of persons who are taking antipyrin or salicylic acid or the products from which salicylic acid may be derived in the system. The salicylic reaction has a pronounced violet tone which is scarcely liable to be mistaken by the practised eye for the reaction of diacetic acid There is also a purple tone about the colour resulting from the effects of antipyrin. If doubt should exist appeal may be made to the acetone test which will give the conjoint reaction where diacetic acid is present and no reaction where the colour reaction with the ferric chloride is not due to diacetic acid

If no reaction is given with the ferric chloride test oxybutyric acid need not be looked for As an indicator of the presence of oxybutyric acid the polarimeter is employed and its result is compared with the result given by cupric oxide reduction. Oxybutyric acid possessing levo-rotatory power neutralises the dextro-rotatory effect of the dextrose and throws out, in proportion to the amount present the concord between the figures derived from the two methods of estimation. In the absence of oxybutyric acid the accord between the polarimetric and cupric oxide reduction estimations is often very close and should never deviate to any significant extent. It is true, as shown by the examination of urines giving no ferric chloride reaction and therefore assumedly not containing oxybutyric acid, that a certain amount of difference attributable to the incidental presence of some other levo-rotatory body may be found, but it is not likely to reach a point that can be considered to be worth attention. Levulosuria and pentosuria are conditions so rarely come across that they are not here taken into account. Hence for clinical purposes the difference between cupric oxide reducing power and optical activity may be read off not only as an indicator of the presence but also as giving a representation of the amount of oxybutyric acid present. This may be expressed either in terms of dextrose by simply subtracting the lesser dextrose value obtained by the optical method from the greater obtained from the reduction method or in terms of actual oxybutyric acid which has an optical activity of 24 1° as against that of dextrose 52 5, by multiplying the above difference by 2·2.[2]

In connexion with the very large quantity of oxybutyric acid that has been stated by some authorities to have been found by the above-described method of estimation, Magnus Levy[3] in an elaborate dissertation on oxybutyric acid and its relation to diabetic coma, has raised the question of the validity of the process He brings forward work conducted upon other lines and states that the quantity of oxybutyric acid that can be extracted by ether from the acidified urine comes out much less than that deducible from the difference between optical activity and cupric oxide reducing power, but agrees fairly with the amount given by calculation founded on determining the saturating capacity of the bases and noting the deficiency in the mineral acids present to effect saturation, the deficiency being reckoned as due to oxybutyric acid Many elements of consideration, with risk of error, are here involved and the results must be looked upon as blended with uncertainty He points out that the levo-rotatory effect of the urine is increased by an excess of the lead acetate used in the preparation for examination This is easily shown by observation to occur, even to a considerable extent, when much lead acetate is present and unless guarded against may give rise to considerable error Possibly some of the earlier results recorded may have been vitiated in this way and too high figures given but the fallacy may be escaped from with proper procedure as regards the amount of lead acetate used, and frequently the urine is sufficiently devoid of colour for filtration alone to suffice, in which case there can be nothing to interfere with correctness of result.

Should it be thought desirable the dextrose may be fermented off so as to leave the oxybutyric acid with its levo rotatory power freed from any neutralising influence when a simple polarimetric reading suffices to give the information required. The process, however, is lengthy and tedious and, I cannot help thinking, involves the risk of a certain amount of loss of the oxybutyric acid present I am of opinion that with recourse to the cupric oxide reduction and optical activity method we need not go further and that information is supplied by it upon which reliance may be placed

We come now to the question of harm inflicted by this chain of principles None of them, as shown by experiment, is capable *per se* of exerting any pronounced or immediate toxic effect and to none of them can diabetic coma be considered directly attributable Acetone being volatile has a channel of escape by the lungs in addition to that afforded by the kidney As is well known in the bad form of diabetes it is strongly perceptible in the breath

(To be continued)

THE SUBCUTANEOUS INJECTION OF CINNAMATE OF SODIUM A NEW DEPARTURE IN THERAPEUTICS

BY LOVELL DRAGE, M D OXON

With a Note on the Preparation of Cinnamate of Sodium Solutions suitable for Hypodermic Injections

BY GILBERT T MORGAN, D SC LOND, F I.C

AFTER many years' wandering in search of an explanation of the intravascular clotting which is observed in the human body in connexion with a variety of conditions I have come to the conclusion that a partial explanation only can be found on strictly chemical and physical grounds. There has always appeared at the moment when a complete "explanation" has seemed possible a factor of unknown quantity The same difficulty appears in all phenomena when a vital process is involved. We are, indeed, very far off an accurate conception of the meaning of the term *life* and one is forced to the conclusion that when a process is connected intimately with living cells there is a limit to human comprehension.

Speculation leading to a working hypothesis seems at the present moment the only means within our reach of arriving at solutions of many of the phenomena, if not all, which are connected with disease Having arrived at a working hypothesis as to the causes of the intravascular clotting which occurs during the lying in period of women I have been led into a speculation as to what is the constituent of the blood which is the cause of the *impasse* at which I had arrived What is the constituent which shows pre-eminently the phenomena associated with living cells? Surely, it is the white blood cell.

Accepting as I do the conclusions to which Dr J G Adami arrived in his article on Inflammation in Dr Clifford Allbutt's "System of Medicine," it is no matter of surprise that I have been assiduously looking out for weary years for a gleam of light which would help me to understand the reason why certain drugs have an influence upon such diseases as cancer and tuberculosis A recent article in the *Journal of Pathology* on the leucocytic changes following injections of cinnamate of sodium has given me a clue. Inflammation, in the words of Dr Adami, is the series of changes constituting the local manifestation of the attempt at repair of actual or referred injury to a part—or, briefly, as the local attempt at repair of actual or referred injury

The injection into veins of cinnamate of sodium has now been shown by Dr H Batty Shaw—as it had been previously by Richter and Spiro—to produce a general leucocytosis, not by depriving the blood of a certain amount of liquid, but by stimulating the simpler lymphocytes to transformation into polymorphonuclear cells and intermediate forms The oil of cinnamon was one of the drugs the action of which I was previously not in a position to understand, and I naturally inclined to a trial of the cinnamate for the same conditions of disease as those for which I had previously exhibited the oil. A drug capable of producing leucocytosis, such as the cinnamate of sodium, appeared to me to be the very one which would be likely to be of avail in the repair of tissue damaged by inflammatory, tuberculous or cancerous processes, because it is the leucocyte of one kind or another which is at once the agent of destruction and repair

It is the purpose of this paper to place before my professional brethren (having briefly indicated the foundation of my belief in the efficacy of my method of treatment) the result of my observations of the action of the cinnamate of sodium in various conditions of disease For purposes of administration I use a 10 per cent solution of cinnamate of sodium in glycerine. This was prepared for me by Dr Morgan of the Royal College of Science, South Kensington, who has very kindly promised to write a note dealing with the chemistry of the subject.

CASE 1 —The first case which I selected for trial was that of a man, over 60 years of age, who was much emaciated and who was apparently dying from tuberculosis of the lungs. His weight was only seven stones and 10 pounds at the time of the commencement of treatment, he had lost two pounds at the end of the next fortnight After this he ceased to lose weight. The expectoration was excessive in amount, but was reduced after one injection of 15 minims of the solution into the skin close to the edge of the scapula, and is now, a month later, very small in amount

CASE 2 —The next case treated was that of a man, over 60 years of age, who was going downhill very rapidly He is, I believe, suffering from cancer of the pancreas, at all events he has had the symptoms usually noted when this organ is so affected At the time of the first injection into the abdominal walls vomiting was incessant and he suffered great pain He was very much emaciated. He has had two injections of 30 minims each twice a week Vomiting has been completely controlled, the pain is very much alleviated, and the delirium, which was beginning to be troublesome, is now, after three weeks' treatment, absent.

CASE 3 —The next case was that of a man about 30 years of age, suffering from chronic inflammatory mischief connected with the middle ear This man came under my care some months ago with a history of inflammatory trouble connected with both ears, following upon influenza. He had been treated by throat and ear specialists The tympanum on one side was perforated and he used this ear alone with the aid of a trumpet. He was completely deaf on the other side and suffered acute pain, having reduced the pain with leeches I persuaded him to consult Mr Cumberbatch who gave a very gloomy report of the condition of the ear and suggested continuous blistering and the use of a spray for the nose The patient did not improve and I persuaded him

[3] Ibid, Band xlii 1899

to allow me to inject 30 minims of the cinnamate solution behind the mastoid. In a fortnight's time he returned for a second injection in high spirits, the improvement in hearing was very marked and I now look forward to a complete cure.

I have now under treatment one early case of laryngitis, almost certainly tuberculous in which the evening temperature was at once lowered after an injection of 30 minims and there was a diminution in the amount of expectoration

I am quite aware that these preliminary and unfinished cases do not furnish absolute evidence as to ultimate success, but the results have been so extremely striking to me that I have felt it my duty to give my professional brethren the opportunity of extending observations upon the value of the drug There are many points connected with the use of the drug which require time and the efforts of a large number of observers. I have not injected more than 30 minims of the 10 per cent. solution, but it is probable that a much larger dose can be used safely I have not at present done so because the dose with which I have worked gives good results and causes no unpleasant symptoms to the patient. It is probable that there are many other chemical substances which may be used to produce similar effects I feel some degree of assurance that the lines upon which such diseases as cancer and tuberculosis can be treated successfully are those based upon the principle of administering drugs which by their action on the white blood cells will assist repair in the cells damaged. At any rate I am confident that I am calling the attention of the medical profession to a valuable therapeutical method

NOTE BY DR. GILBERT T MORGAN

The therapeutic application of sodium cinnamate described in the preceding communication was rendered practicable by the discovery that this salt dissolves in glycerine to form a clear solution which can be easily manipulated in the hypodermic syringe. This observation was the outcome of my own experiments on the solubility of the substance in various media, an investigation which was undertaken at Dr Lovell Drage's suggestion

This preparation is more reliable than the emulsions already employed in physiological research, inasmuch as these mixtures alter in composition by subsidence in a comparatively short space of time whereas the glycerine solution remains unchanged for an indefinite period The glycerine solution is prepared by heating dry powdered sodium cinnamate with the pure solvent at a temperature of 180° C. (about 360° F) and in this way from 10 to 11 per cent. solutions are readily obtained It is important that the salt should be finely divided in order that the dissolution may proceed as quickly as possible because prolonged digestion of the solvent at the temperature indicated leads to the formation of acrolein (acraldehyde) a substance having very irritating properties More concentrated glycerine solutions may be produced but these exist at the ordinary temperature in a state of supersaturation and the salt gradually crystallises out, the separation being accelerated by agitation. The high temperature required for the preparation has the useful effect of ensuring the sterilisation of the solution.

Further experiments showed that sodium cinnamate is almost insoluble in chloroform acetone ether absolute alcohol and other low boiling point organic solvents Boiling water dissolves a large amount of the salt (about 25 per cent.) but the greater portion of the substance crystallises out on cooling a sediment is slowly formed in 10 or 12 per cent. solutions, the supernatant liquid being distinctly alkaline to litmus paper

Ethyl acetate ethyl benzoate and ethyl cinnamate dissolve appreciable quantities of the salt but the solutions are too dilute for practical purposes Hot oleic acid takes up a large amount of the cinnamate, but the greater part of the salt separates out again on cooling to form with the solvent a viscid emulsion.

It is, indeed a fortunate circumstance that glycerine is the most suitable solvent for the cinnamate, because this liquid has other properties which combine to make it a particularly useful medium for the subcutaneous introduction of the drug firstly *it is very inert* and *secondly it is* miscible with water or aqueous solutions A gradual addition of water to the glycerine solution would take place in the tissues into which the liquid is injected, bringing the salt into intimate contact with the parts affected.

The further study of other preparations of cinnamic acid and its derivatives is in progress

THE HETOL TREATMENT OF TUBERCULOSIS

BY DR. O AMREIN

IN 1888 Professor Landerer of Stuttgart proposed a new treatment of tuberculosis and 10 years afterwards he published in a large volume[1] his technical and physiological observations and the results which he obtained Landerer holds the opinion that the tuberculous affections have little tendency to heal owing to the want of blood vessels which is very unfavourable to the process of cicatrisation. Therefore he tries to provoke an artificial hyperæmia" in the neighbourhood of the tubercle nodules by injecting cinnamylic acid[2] into the circulatory system and he observes an inflammation and accumulation of leucocytes round the tuberculous foci (state of leucocytosis). The next stage is emigration of multinuclear leucocytes into the alveolar septa and organisation of blood vessels (state of organisation). In the next place new vessels and fibrous tissue grow through the tubercle nodules (state of vascularisation) and finally this new fibrous tissue becomes solid and the result is a cicatrice (state of cicatrisation and retraction) He thinks that this healing process is similar to the natural one, only quicker and more solid. Instead of the cinnamylic acid Landerer afterwards used the cinnamylic soda salt and called it hetol.' Further publications (Krämer) show that the principal action of the hetol treatment is the leucocytosis (therefore everything causing a leucocytosis would be a help in combating tuberculous diseases) This method of Landerer has been tried by a great many physicians and notwithstanding great opposition at the time of its introduction it has become a very well known one in Germany and Switzerland. But up to the present time much discussion favourable and unfavourable has occurred. *As against the good results published by Landerer* himself and other authors (Heusser Krämer &c) is to be set the fact that other physicians did not find the expected effect. I mention here especially the publication by Dr H Staub (at the sanatorium Wald Zürich) in No 12, 1901 of the *Correspondenzblatt für Schweizerärzte* and the discussion between him and Dr Heusser of Davos in the same medical paper

As the observed results of many cases can alone enable medical men to decide as to the efficacy of the treatment I here bring forward my results obtained by hetol treatment in the period 1899-1901. I learned the method (intravenous injections) at the Sanatorium Wald in 1899 and I have used it in the manner described by Dr Staub In the first place, I may say that I have never observed any harmful influence either on the local state of the lungs or on the general state of health of the patient. There was never any inflammation at the place of injection. In one case however (Case 13) every injection caused pruritus cutaneus on the chest after from three to four hours lasting about half an hour, accompanied by fever I always began with one milligramme (0·001 gramme) I injected the hetol every third day and increased the dose after two injections of a similar dose by one milligramme until 10 milligrammes had been reached then by two and a half milligrammes until from 20 to 25 milligrammes (maximal doses) had been reached using a solution of 1 per cent. up to 10 milligrammes and a solution of 5 per cent. from 10 milligrammes to from 20 to 25 milligrammes. A stasis of blood in the veins of the arm was caused by an elastic ligature and after disinfection by spiritus saponatus and sublimate the injection was made into the vena mediana cubiti. The temperature was taken at 7 A.M. 9 A.M and at 12 noon and at 2.30 P.M. 4 P.M 6 P.M and 9 P.M in the mouth (10 minutes) and the above mentioned dose was increased only after the temperature did not exceed 37·3° C During menstruation the injections were not stopped on female patients

The accompanying table, constructed after the example of Dr Staub gives all the observed effects of the treatment, and also all details—the state of the disease and its complications the number of days of general treatment the number and dose of the special injections the temperature,

before and after the "cure," the bacilli before and after the "cure," the weight gain or loss, the local success, &c.

It will be seen that real positive success was obtained in four cases out of the 13 (Cases 1, 2, 4, and 11), but as all patients have been undergoing a cure the whole time in the high altitudes (nine of them at Davos Claendal and the others at Arosa) it is quite impossible to say whether these results are caused by the injections or not, and whether they could not have been obtained by the climatological and dietetic treatment alone I must say that they are not at all different from some cases of mine of similar character in which the patients were not injected.

Of great interest are Cases 3 and 5 Both of these patients were young women, rather stationary cases, who had been at Davos already for one and a half years and nine months respectively without improving Certainly if after the injection cure they had shown an improvement it must have been caused by these injections. But neither showed any quicker or greater improvement.

One patient (Case 9) lost the fever (at the beginning 38 2° C) after some weeks, but was lying in bed all that time In this case the lessening of the fever seemed to me to be brought about more quickly than I observe generally One patient (Case 3) got fever during the injection cure, but after an acute and bad bronchitis, and did not lose it again With regard to the eight patients with bacilli in the sputum at the beginning one lost them after some weeks and the others kept them. No patients with "closed tuberculosis" showed bacilli during the injection cure. The patient in Case 13 got a temperature of 38 9 C after the injection of one milligramme, and after an interval of a week again after the same dose, with much expectoration and pruritus cutaneus on the chest (above mentioned), so that the injections were not continued It was a bad case with cavities and caries of the ninth right rib (this was successfully operated on later) Cases 10, 12, 13, and 4 always showed an increased expectoration on the day after the injections I have never observed any hæmorrhage [3]

The only positive success that I could remark, therefore, was the lessening of the fever in Case 9 Certainly this one case cannot tell us if we must say "*Post hoc ergo propter hoc*," but as I mentioned the lessening of the high temperature occurred more quickly than usual (I may observe that Dr Lips of the Sanatorium Wehrawald wrote to me in a letter dated Oct 4th, 1901, about a patient whom he was sending to Arosa, that by the hetol treatment the temperature, from being irregular and high, became constant and normal.)

Besides that my table shows about the same results as the above mentioned paper by Dr Staub no harmful influence was apparent, and, on the other hand, I never could see any positively good effect which I could not explain myself by the climatological (altitude) and hygienic and dietetic treatment.

Arosa Switzerland

AN EXPLANATION OF THE CAUSE OF INEQUALITY OF PUPILS IN CASES OF THORACIC ANEURYSM

BY R. CECIL B WALL, M A., M D OXON,
M R.C P LOND,
MEDICAL REGISTRAR AT THE LONDON HOSPITAL
AND
E W AINLEY WALKER, M A., M D OXON,
GORDON LECTURER IN EXPERIMENTAL PATHOLOGY AT GUY'S HOSPITAL
LATE RADCLIFFE TRAVELLING FELLOW IN THE UNIVERSITY
OF OXFORD

THE RECEIVED EXPLANATION OF ANISOCORIA IN THORACIC ANEURYSM IS UNSATISFACTORY

HITHERTO the accepted explanation of the inequality of the pupils which so frequently occurs in cases of aneurysm of the thoracic aorta has supposed that there is some interference with the normal activity of the sympathetic nerve But for long it has been noticed that there might be inequality of the pupils, although there was no evidence of implication of that portion of the nerve trunk containing dilator fibres for the pupil. It was therefore supposed that some influence was exerted through the nerve filaments of the sympathetic which supplied the sac wall of the aneurysm. On examining cases of thoracic aneurysm in which the phenomenon was present it became obvious that the received explanation was unsatisfactory, both on anatomical and physiological grounds. The original theory seemed to be definitely disproved by such a case as that of Case 4 (*infra*) in which though the pupils were unequal the aneurysms sprang from the first part of the arch of the aorta, and did *not come into relationship with that part of the sympathetic* trunk which contained the fibres that supply the iris The modification of the theory which supposes influences to be transmitted through the sympathetic filaments which supply the sac wall accepts the premiss that such filaments exist. In the majority of cases of aneurysm that are of considerable size the sac wall consists, to a very large extent, not of the original arterial coats but of the surrounding structures compressed or eroded. In such cases a very great part of the sac wall must be without any *special sympathetic* nervous supply, it follows therefore that the premiss upon which this theory is based may possibly be unsound.

---

[3] About the leucocytosis which should be a very great one after the injections (Landerer) I made some experiments in 1900 at Davos Claendal On two patients (Case 8 in the table and a physician whom I treated with hetol and who was already in a state of relative healing (not mentioned in the table) I found the greatest leucocytosis four hours after the injections (using the apparatus by Thoma Zeiss) and greater when a meal was taken between the injection and the blood analysis, but never exceeding more than 11 000 leucocytes in one cubic millimetre. Experiments on myself showed nearly the same great leucocytosis after a big meal I never saw an increasing of the leucocytes to the double number or more as Landerer is said to have seen

The objections on physiological grounds to this nervous theory are even more weighty As far back as 1858 Ogle noticed that though in most cases in which the pupils were unequal the left was the smaller yet this was not the invariable rule. He put forward the view that sometimes stimulation and sometimes paralysis of the sympathetic was the mechanism by which this observation could be explained In some cases it is true, it is possible to conceive that such conditions may be present, but in most so much hypothesis incapable of proof is necessary that the explanation ceases to afford satisfaction. At the best the theory involves the proposition that though the mechanism *in two cases* is similar yet the effect of its operation may be one of two results diametrically opposed.

The objection however that is most fatal to this theory is based upon the fact that though inequality of the pupils is quite common in thoracic aneurysm yet other signs of interference with the sympathetic system are of extreme rarity Claude Bernard in 1852 investigated experimentally the action of the sympathetic not only with regard to its influence over the iris but also with regard to its other functions. Since then many cases have been recorded in which the trunk of the sympathetic has been affected by external influences and in these cases not only are there pupillary changes but also vaso-motor and other phenomena. Thus in a case which was admitted *to the London Hospital* in 1901 under the care of Mr P Furnivall the implication of the left sympathetic in a new growth was associated not only with diminution in the size of the left pupil but also with a complete loss of power to dilate on shading and a partial loss on the *instillation* of cocaine in addition there were some enophthalmos and pseudoptosis on the left side with anidrosis as tested by pilocarpine on the left side of the face and neck. In those cases in which inequality of pupils occurred in association with aneurysm of the thoracic aorta no instance was found in which there was any interference whatever with the normal pupillary reflexes, nor was there any case in which there was enophthalmos exophthalmos, pseudoptosis or retraction of the lids, nor any in which there was recognisable abnormality of the vaso-motor or sweat gland systems. Sir William T Gairdner in Allbutt's 'System of Medicine" in an article upon aneurysm is apparently so convinced that inequality of the pupils associated with thoracic aneurysm is in all cases due to implication of the sympathetic that he writes *There need be little* hesitation in affirming that the Argyll Robertson pupil will be found as characteristic of the cases depending on thoracic or aneurysmal tumours as it is of the other forms of spinal myosis." If the inequality of the pupils were *due in all cases to* implication of the sympathetic Sir W T Gairdner's statement would be correct in a long series of cases however no example has been found in which the Argyll Robertson pupil was present or any of the other phenomena usually associated with interference with the *sympathetic*. It is also a matter of common knowledge that myosis of nervous origin is usually extremely well marked, whereas the inequality of the pupils associated with thoracic aneurysm is seldom great and often only demonstrable when the pupils are moderately dilated in a dim light.

In view of these difficulties it seemed necessary to seek some other possible cause for the inequality of the pupils and the possibility of vascular conditions affecting their size was submitted to investigation.

VASCULAR CONDITIONS MAY INFLUENCE THE SIZE OF THE PUPILS.

It is well known that in acute inflammation of the iris the pupil is small, this is in all probability due to vascular turgescence, though conceivably it might be the result of nervous influence. In cases, too in which the general blood pressure is markedly increased—for instance, in chronic interstitial nephritis—*it is extremely common to find small* pupils. On the other hand, most states in which the blood pressure is low are characterised by large pupils examples are to be found in cases of typhoid fever or chlorosis Syncope also which as Dr Leonard Hill has shown is associated with a determination of the blood into the portal area, is characterised by enlargement of the pupils. These examples are sufficient to suggest that probably the size of the pupils is not always entirely controlled by nervous influences. Vascular conditions may also partly if not wholly explain the large pupil of chronic glaucoma or the contracted pupil found associated with lowering of the tension of the aqueous humour in cases of punctured wound of the cornea.

In considering the effect of vascular conditions upon the size of the pupils it at once occurs that mere vascular turgescence is insufficient to produce myosis, if this were the case the pupils should be minute in all cases of venous engorgement—for instance, in heart failure. Often, however in such cases, though the veins of the head and neck are distended the pupils are large. It does not seem to be true that the mere filling of the iris with blood will lead to narrowing of the pupil. On the other hand, there is some definite relationship between the arterial blood pressure and the size of the pupil. This relationship is probably to be explained by the anatomical peculiarities of the vessels of the iris, as Waller originally showed they are spiral or zigzag so that during contraction or dilatation their lumen is not changed in calibre. *It is a well known physical fact* that the raising of the pressure in a fluid contained in a flexible spiral tube tends to cause elongation and straightening of the tube.[1] From this it follows that a rise of blood pressure in the spiral vessels of the iris would tend to lengthen them and to lead to narrowing of the pupil, and *vice versâ* a fall of blood pressure to shortening of the vessels and enlargement of the pupil In the same way perhaps, may be explained in part the alteration in the size of the pupil associated with changes of tension in the aqueous humour as in glaucoma or punctured wounds of the cornea.

If then alterations in the general arterial blood pressure can lead to changes in the size of the pupils inequalities in *the local blood pressure may be expected to lead to* inequalities in the size of the pupils Local inequalities of blood pressure are of common occurrence in cases of aneurysm, inequality of the radial pulses is frequently noted and inequality of the carotid or temporal pulse perhaps only less frequently because less often sought. Such differences in the volume of the pulse are not infrequently the result of conditions obtaining which facilitate or retard the flow of blood from the aorta into one or other of the great vessels and the inequality may also exist in the vessels of the iris if the presence of atheromatous degeneration in the circle of Willis prevents rapid equalisation of blood pressure in that region. It seemed, therefore that the anisocoria met with in some cases of thoracic aneurysm might be sufficiently explained by unilateral alterations in blood pressure. It has been our endeavour to submit this view in the first place to the test of clinical experience and secondly to find experimental proof of its validity

EVIDENCE BASED UPON CLINICAL OBSERVATION

If in a case of thoracic aneurysm the pupils and the radial pulses are unequal it is commonly found that the radial pulse is greater on the side on which the pupil is smaller Thus, taking *from* the records of the London Hospital 26 consecutive cases of inequality of the pupils associated with thoracic aneurysm occurring during the last four years in which definite notes were made concerning the relative size of the radial pulses and of the pupils it was found that in 11 *cases the radial pulse was larger on the side on which the* pupil was smaller, in eight the radial pulses were stated to have been equal, and in seven the larger pulse and the larger pupil were stated to have been on the same side. The observation, as a rule, was made by the clinical clerk to the case. It does not necessarily follow that because there is inequality of the radial pulses there must necessarily be a similar inequality in the ophthalmic arteries. It seemed that there would be less risk of fallacy if the relative size of the temporal arteries was recorded and compared with the size of the pupils, since the observations have been thus recorded it has been found to be extremely common for the smaller pupil to correspond to the larger temporal pulse In fact, up to the present time no negative example has occurred in our experience.

---

[1] This fact is illustrated in the familiar instruments Bourdon's steam-pressure gauge and Fick's spring kymograph

The following cases may be taken as examples —

CASE 1. *A case of aneurysm of the second and third parts of the arch of the aorta in which the right pupil was greater than the left and the left radial pulse greater than the right*—A male patient was admitted into the London Hospital in 1900 under the care of Dr Percy Kidd with signs of an aneurysm of the transverse arch of the aorta pressing upon and obstructing the left bronchus and also causing paralysis of the left recurrent laryngeal nerve The right pupil was then larger than the left, the left radial pulse was readily felt but the right was scarcely palpable. Both pupils reacted to light and with accommodation Unfortunately, no note was recorded as to the comparative size of the temporal pulses He was readmitted in 1902, under the care of Dr H Head, with similar signs and shortly afterwards died At the post-mortem examination a large aneurysm was found involving the transverse arch and the upper half of the descending thoracic aorta, this had pressed upon the œsophagus and the left bronchus and had eroded the third, fourth, and the fifth dorsal vertebræ, the orifice of the innominate artery had obviously been pressed upon and obstructed

CASE 2. *A case of aneurysm of the transverse arch of the aorta in which the left pupil was greater than the right and the right temporal and radial pulses greater than those on the left side*—A male patient was admitted to the London Hospital under the care of Dr A. E Sansom with the signs of aneurysm of the transverse arch of the aorta. The left pupil was greater than the right and the right radial pulse was greater than the left, on the left side the temporal pulse was scarcely palpable whereas on the right side it was easily felt. The pupil reactions were normal Death resulted from rupture into a bronchus and at the necropsy the aneurysm was found to be of the transverse arch of the aorta, eroding the bodies of the third, fourth, and fifth dorsal vertebræ and compressing the apex of the left lung This case is also of interest in that though the aneurysm was in relation to the trunk of the sympathetic on the left side, yet the left pupil was greater than the right and there was no evidence of sympathetic paralysis

CASE 3. *A case of aneurysm of the first part of the arch of the aorta in which the right pupil was greater than the left and the left radial pulse greater than the right*—A male patient was admitted to the London Hospital in 1901 under the care of Dr A. E. Sansom with a pulsating fluctuating swelling in the second and third right intercostal spaces which was diagnosed as an aneurysm of the first part of the arch of the aorta. There was no laryngeal paralysis. The right pupil was greater than the left and the left radial pulse was greater than that on the right Both pupils reacted to light and with accommodation

CASE 4 *A case of aneurysm of the arch of the aorta in which the right pupil was greater than the left and both temporal and radial pulses on the left side greater than those upon the right*—A male patient was admitted to the London Hospital in 1901 under the care of Dr Stephen Mackenzie with the signs of an aneurysm of the first part of the arch of the aorta and of pulmonary tuberculosis at the right apex. The right pupil was sometimes equal to, and sometimes larger than, the left, the temporal and radial pulses on the left side were greater than those on the right. Both pupils reacted to light and with accommodation At the necropsy there was found to be extensive pulmonary tuberculosis at the apex of the right lung and two aneurysms sprang from the first part of the arch of the aorta, one passing into the right lung and the other passing back into the posterior mediastinum Neither of these aneurysms came into relation with the trunk of the sympathetic nor were there any signs of interference with its function.

It is unnecessary to multiply examples, these cases will suffice as instances of enlargement of the pupil upon that side upon which there is presumptive evidence in favour of some obstruction of the blood flow and absence of any evidence of interference with the sympathetic

In the next place clinical evidence was sought to show the effect of obstruction of the carotid vessels in the neck These cases serve to confirm the accuracy of the other observations

CASE 5 *A case of aneurysm of the innominate artery in which the right pupil was greater than the left and the left temporal and radial pulses greater than the right*—A female patient was admitted to the London Hospital in 1902 under the care of Dr A. E Sansom There was a pulsating swelling at the root of the neck on the right side, the temporal and radial pulses on the right were smaller than those on the left, and the right pupil was greater than the left

CASE 6 *A case in which the right common carotid was tied for aneurysm in the innominate artery*—A patient was admitted to the London Hospital in 1901 under the care of Mr Waren Tay with an aneurysm at the root of the neck in the right side The pupils were then equal. Distal ligature of the common carotid was performed by Mr T H. Openshaw After the operation the right temporal pulse could not be felt and the right pupil was larger than the left, and so remained

CASE 7 *A case in which the left common carotid was tied for primary hæmorrhage*—A boy, aged 12 years, was admitted to the London Hospital in 1902 under the care of Mr C W Mansell Moullin suffering from a wound of the left common carotid artery which had been inflicted by some broken glass The artery was ligatured but the hæmorrhage had been so great that the patient died two hours later After the ligature the left pupil was found to be greater than the right and so remained until death

Summary of the Cases

Case	Diagnosis	Larger pupil	Larger pulse.
1	Aneurysm second and third parts of aortic arch	Right	Left (radial)
2.	Aneurysm of transverse arch	Left	Right (radial and temporal)
3	Aneurysm of first part of arch	Right	Left (radial)
4	Aneurysm of first part of arch	Right	Left (radial and temporal)
5	Aneurysm of innominate artery	Right	Left (radial and temporal)
6	Ligature of right common carotid artery	Right	Left (temporal)
7	Ligature of left common carotid artery	Left	Right (temporal)

EVIDENCE BASED UPON EXPERIMENTS

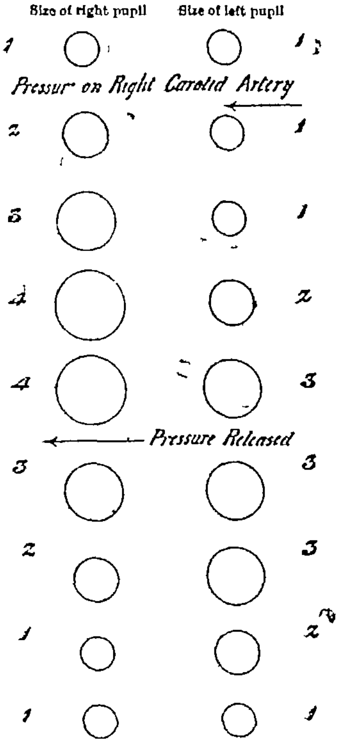
In order to test the accuracy of the clinical evidence experiments were made on animals Rabbits were chosen for the purpose of the observations and the results obtained were briefly as follows

EXPERIMENT 1.—If a rabbit be anæsthetised and its carotid artery be exposed and separated from its sheath compression of the artery sufficient to abolish circulation through it may produce an alteration of the pupil The effect, if any, is an enlargement of both pupils. This is by no means constant, but is best seen with pupils moderately contracted at the outset. The change produced is slight. Whether it is absolutely synchronous in both pupils could not be definitely determined owing to the impossibility of watching both the eyes of a rabbit at the same time It is, however, not markedly asynchronous

EXPERIMENT 2—If the animal be now killed and water forcibly injected into one carotid artery the pupil on that side diminishes in size. The amount of diminution which can thus be caused is considerable in degree, but not extreme, and is more marked in an originally dilated pupil than in one which was already contracted This is in accordance with our clinical experience in comparable cases The alteration is entirely independent of intra-ocular tension occurring equally well after crucial incision of the cornea and removal of the lens in the dead animal The effect of such injections is entirely unilateral. It follows that unilateral alterations of intra vascular pressure can cause considerable variations in the size of the pupil. And we were led to attribute the fact that closure of one carotid artery does not produce in rabbits a marked or even definite inequality of pupil to the influence of two factors: first, that the communication between the vessels at the base of the brain appears to be extremely free, so that a unilateral fall of pressure is almost instantly felt equally on the two sides and both the pupils undergo a slight enlargement; and secondly that in the lower animals the vertebral arteries play relatively a much greater part in the arterial supply than is the case in man. Thus even in dogs as shown by Dr. Leonard Hill the vertebral arteries alone can perfectly maintain the cerebral circulation.

It therefore seemed advisable to try the same experiment in a suitable animal after one or both vertebral arteries had been ligatured. This procedure was however made unnecessary by the discovery that we could invariably produce the desired result upon ourselves by the unilateral compression of the artery. And the same facts have been observed on others.

EXPERIMENT 3.—If digital pressure be applied to one carotid artery sufficient to abolish or considerably reduce the temporal pulsation on that side the following events present themselves (see Figure). The pupil on the same side gradually enlarges and it remains enlarged so long as pressure is maintained. A little later an enlargement of the opposite pupil follows. This pupil eventually reaches the size of that upon the side of pressure in certain individuals but does not usually do so. Ordinarily a condition is obtained in which both pupils are larger than before, and that upon the side of pressure definitely larger than the other. On now releasing pressure both the pupils gradually regain their normal size, that on the side of pressure lessening distinctly earlier than its fellow. In this experiment we attribute the enlargement of the pupil on the same side to the immediate fall of pressure in the ocular vessels which results from the compression of the carotid artery. The subsequent enlargement on the opposite side is due to the general fall of pressure in the circle of Willis which results from the same cause. In the majority of individuals, as we believe, the communication at the base of the brain is not sufficiently free to equalise this pressure after the closure of one carotid artery in the neck, and inequality of pupils is the consequence. In cases of aneurysm this is likely to be even more marked in consequence of the atheroma usually associated with them; this would considerably affect compensatory flow through the communicating arteries, rendering them rigid and less easily dilatable. Where ultimate equality of the dilated pupils shows itself in this experiment it is probably due to an unusual freedom of communication through these communicating vessels in the individual concerned. The phenomena in question are not due to pressure on the sympathetic in the experiment, for other evidences of its paralysis are conspicuously absent and both the pupils share in the effect. Nor are they due to a cervical reflex for the enlargement is asynchronous and asymmetrical and similar pressure may be made upon the neck allowing the carotid artery to slip aside without producing any such result. That they are vascular in origin is further shown by the fact that on release of pressure the return diminution of the pupils occurs by a series of small waves or oscillations synchronous with the pulse in the carotid. The left carotid artery will usually be found the easier for the purposes of demonstrating these results, but they are readily obtained with either. In cases of aneurysm with unequal pupils we find that pressure on the carotid artery on the side of the small pupil results in its enlargement. That this effect is purely vascular is again suggested by the fact that one such patient volunteered the statement that he temporarily lost the vision of the eye concerned while the compression lasted. Both on clinical and on experimental grounds then it seems reasonable to suppose that inequality of the pupils may be the result of local inequalities of blood pressure and seeing that in many cases of thoracic aneurysm such conditions obtain while evidence of implication of the nervous system is entirely absent, it is justifiable to conclude that anisocoria when present is due not to nervous but to vascular conditions.



Diagrammatic view of effect of pressure on the carotid artery upon the pupils. The figures 1, 2, 3, 4 indicate varying sizes. At the commencement both pupils are the same size. Pressure being made on the right carotid artery the right pupil dilates, the left pupil remaining the normal size. As the pressure is kept up the left pupil gradually dilates until it becomes nearly as large as the right. On the pressure being relaxed the right pupil soon contracts. The left contracts also but much more gradually.

GENERAL SUMMARY.

A.—The explanation which ascribes the anisocoria at times occurring in cases of thoracic aneurysm to interference with the sympathetic is unsatisfactory. 1. On anatomical grounds (*a*) because in the majority of cases there is no evidence of implication of that portion of the sympathetic nerve trunk containing pupil dilator fibres; and (*b*) because it is not established that sympathetic filaments supply the sac wall of an aneurysm. 2. On physiological grounds (*a*) because the explanation supposes that the same conditions may produce sometimes irritation and sometimes paralysis of the nerve; (*b*) because cases are rare in which there is any evidence apart from the pupillary change that the sympathetic is involved; and (*c*) because the pupillary changes are not those met with in cases where the sympathetic is involved.

B.—1. Alterations in vascular conditions may be associated with alterations in the size of the pupils: (*a*) High arterial tension is associated with small pupils; and (*b*) low arterial tension is associated with large pupils. 2. The physical explanation of this phenomenon is probably to be found in the spiral structure of the vessels of the iris.

C.—Local inequalities of blood pressure may therefore be associated with inequalities of the pupils: (*a*) Clinical evidence. 1. Enlargement of pupils is frequently associated with diminution of the temporal and radial pulses on the same side of the body. 2. Obstruction of the carotid artery on one side of the neck is associated with enlargement of the pupil upon the same side. (*b*) Experimental evidence. 1. Obstruction of the carotid in rabbits is associated with enlargement of the pupils on both sides owing to the freedom of circulation at the base of the brain. 2. Injection of water into a carotid artery of a dead rabbit causes narrowing of the pupil upon the same side. 3. Digital compression of the carotid artery in the human subject is associated with enlargement of the pupil upon the same side.

CONCLUSION

Inequality of pupils associated with thoracic aneurysm is usually due to inequality of blood pressure in the ophthalmic arteries resulting from the abnormal vascular conditions

Our best thanks are due to Dr Mackenzie, Dr Sansom, Dr Kidd, and Dr Head, and to Mr Waren Tay, Mr Mansell Moullin, and Mr Furnivall for permission to record the cases quoted. The experimental work was done in the Gordon Laboratory at Guy's Hospital.

HISTORICAL BIBLIOGRAPHY

1727 Pourfour de Petit (Memoires de l Academie Royale des Sciences 1727, p 1 and Histoire de l Academie Royale des Sciences 1727 p 7) claimed that the sympathetic (intercostal nerve) took origin from the spinal cord and controlled the size of the pupil He described the effect of division of the nerve in animals

1839 Reid (Edinburgh Medical and Surgical Journal, vol xlix p 132, January 1838, and vol lii p 38 August 30th, 1839) repeated and confirmed Petit's experiments and showed that division of the nerve led to contraction of the pupil upon the same side.

1846 Serafino Biffi (Omodei Annali di Medicina, third series, vol xxii pp 630 to 641, vol cxviii the Catalogue of the Library of the Royal College of Surgeons of England) demonstrated the effect of stimulating the peripheral and of the divided sympathetic

1847 Hyrtl (Handbuch der Topographische Anatomie, p 202) claims that vascular conditions cannot affect the size of the pupils for the following reasons: 1 Because the vessels of the head may be engorged and yet the pupil be large N.B The possibility of the size of the pupil varying inversely as the arterial tension has been discussed in the present paper and an attempt has been made to show that venous engorgement, being frequently associated with a fall of the arterial tension may lead to enlargement of the pupils 2. Because after death by decapitation the pupils may be small even though the blood has drained from the vessels N B Hyrtl forgot that the cervical sympathetic must have been divided with the rest of the neck and that myosis of nervous origin would therefore be a probable consequence Langley and Anderson (*vide infra*) accept Hyrtl's statement without further investigation. It is a well known fact that if an animal be bled to death in a simpler way than by decapitation the pupils become large

1853 Walshe (Diseases of the Lungs Heart and Aorta, p 769) described inequality of the pupils in association with thoracic aneurysm but did not suggest an explanation

1854 Brown Séquard (Comptes Rendus de l'Academie des Sciences, 1854 tome xxxviii, p 72) extended and completed Claude Bernard's researches

1855 Gairdner (Edinburgh Medical Journal, August, 1855 p 153) described a case of thoracic aneurysm which at the necropsy was found to have involved the inferior cervical ganglion of the sympathetic in which during life the pupil on the same side had been the smaller of the two and which did not dilate on shading nor completely on the instillation of atropin No mention is made of unilateral changes of temperature sweating, enophthalmos or ptosis but the case seems to have been one of some sympathetic paralysis due to the growth of a thoracic aneurysm

1856 Waller (Comptes Rendus de l Académie des Sciences 1856 tome xliii, p 659) described the spiral or zigzag structure of the vessels of the iris as seen by the microscope in albino rabbits and showed that whether straight when the pupil was small or coiled when the pupil was large their calibre did not vary

1858 Ogle (Transactions of the Royal Medical and Chirurgical Society, 1858 vol xli, p 397) wrote on the influence of the sympathetic on the eye and its appendages This paper is the *locus classicus* for the clinical aspect of the question Ogle collected 27 cases in which there was some abnormality of the pupils in association with aneurysms either thoracic or cervical or with malignant growths in the thorax or neck, or with inflammatory processes in the neck or with injuries of the cervical cord In some of these there can be no doubt but that there was sympathetic paralysis or interference with the cilio-spinal centre In others the evidence is not so clear and Ogle is forced into the explanation that at times there may be an irritation of the sympathetic acting at times directly on the trunk and at times on the sympathetic filaments supplied to the sac wall of an aneurysm It is noteworthy that in the cases where this explanation is necessary there is no record of any sign, beyond inequality of the pupils of implication of the sympathetic Since the publication of Ogle's paper all text-books both English and foreign seem to have accepted his theory as sufficient to explain the anisocoria associated with thoracic aneurysm

1875 Grünhagen and Samkowy (Archiv für die Gesammte Physiologie, x p 165) thought that dilatation of the pupil was caused by action of the sympathetic which acted either (1) by decreasing the quantity of blood in the iris so that it shrinks (2) by contraction of the longitudinal coats of the radially-disposed arteries or (3) by inhibition of the sphincter iridis

1892. Langley and Anderson (Journal of Physiology 1892, vol xiii p 554) in a long and important paper discuss the mechanism of the movements of the iris and conclude that in addition to the sphincter iridis there is a radially-disposed contractile substance not necessarily muscle though for convenience it is called the dilator muscle With regard to some of the points discussed in the present paper they hold that the myosis which results from tapping the anterior chamber may be due to the fact that owing to the reduction of tension the ciliary region of the iris is allowed to come forward We have suggested that it may be partly due to the reduction of the external pressure round a set of spiral vessels in which there is a positive internal pressure Langley and Anderson accepted Hyrtl's views and thought that variations in blood-pressure could not normally affect the size of the pupil They found that by injecting blood and warm saline fluid into the carotid no alteration of the pupil could be obtained in a living animal if however the injection was made in a dead animal and with a carmine injection mass myosis resulted These experiments agree with our own observations which we have attempted to explain as due in the first case to the free anastomosis of the circle and in the second case to an obstruction in that anastomotic ring Langley and Anderson, on the other hand consider that the phenomenon is best explained on the supposition that it is due to stimulation of the sphincter iridis In addition they confirm Waller's account of the structure of the vessels of the iris and give figures showing how during dilatation of the pupil under atropin or stimulation of the sympathetic the vessels become zigzag and retain their normal calibre

PRELIMINARY NOTE ON THE CHEMICAL AND THERAPEUTIC PROPERTIES OF LACHNANTHES TINCTORIA

BY J A. GARDNER, M A. OXON, F I C,
LECTURER ON CHEMISTRY AT ST GEORGE'S HOSPITAL,

HAROLD R D SPITTA, M B DURH, L R C P LOND,
D P H CANTAB,
ASSISTANT BACTERIOLOGIST AT ST GEORGE'S HOSPITAL

AND

ARTHUR LATHAM, M A., M D OXON, M A. CANTAB,
ASSISTANT PHYSICIAN AND LECTURER ON PRACTICAL MEDICINE AT
ST GEORGE'S HOSPITAL AND ASSISTANT PHYSICIAN AT THE
BROMPTON HOSPITAL FOR CONSUMPTION AND
DISEASES OF THE CHEST

LAST December, at the request of Dr P W Latham of Cambridge, we undertook to investigate the chemical and therapeutic properties of the herb lachnanthes Our investigations were considerably delayed at the outset by the facts that it was impossible to obtain either in England or in America more than a few pounds of the plant for nearly three months and that we experienced great difficulty in obtaining really virulent cultures of tubercle bacilli At the present moment we are hampered by the fact that so small a quantity as 10 pounds of the plant has practically exhausted the available supply in England. Comments have been made on this delay and we think it well to issue a statement of the results which we have so far obtained.

The lachnanthes used by us was first submitted for examination to Mr E M Holmes, the curator of the museum of the Pharmaceutical Society of Great Britain, who kindly undertook this duty for us and who certified that the specimens were genuine. The plant was then forwarded to Messrs John Bell and Co of Oxford street in order that an extract might be prepared, and we are glad of this opportunity of expressing our indebtedness to them for the trouble they took in the matter and for the amount of time they gratuitously gave us The lachnanthes was thoroughly exhausted with 70 per cent alcohol and the alcohol was then completely distilled off the solution *in vacuo* and without the aid of heat. The solution obtained in this manner was employed in our experiments

REPORT BY MR. GARDNER.

The extract made by Messrs Bell and Co from seven and a half pounds of lachnanthes herb contained 2 88 per cent. of solids The whole extract, free from alcohol, was precipitated with lead acetate, the precipitate was then washed and decomposed by sulphuretted hydrogen The aqueous filtrate yielded on evaporation a syrup which was soluble in alcohol and also in acetone. The solution in acetone was deep red and on spontaneous evaporation yielded no crystalline matter but dried to a deep-red brittle shellac-like solid. The lead sulphide precipitate was dried and extracted with ether This ethereal extract deposited a small amount of a red solid, whilst the residue on treatment with acetone yielded a further small amount of a yellow deliquescent substance The mother liquor on spontaneous evaporation left a red syrup which constituted the bulk of the extract

After extraction with ether the lead sulphide precipitate was extracted with 94 per cent alcohol, and this extract yielded on spontaneous evaporation two or three grammes of a red crystalline solid, whilst the mother liquid dried to a red tarry matter, soluble in acetone, but which as yet has shown no signs of crystallisation This constituted the bulk of the extract.

The filtrate from the lead acetate precipitate was now precipitated with lead subacetate. The precipitate thus obtained was decomposed by sulphuretted hydrogen as before and filtered The aqueous filtrate contained the bulk of the resinous matter set free, it was evaporated and the residue exhausted with alcohol. A small portion was, however, insoluble in alcohol and was re-crystallised from water The alcoholic extract was evaporated and extracted with water when a small amount remained undissolved. The bulk dissolved and on evaporation yielded a brittle, yellow deliquescent, amorphous solid which was however soluble in water and insoluble in chloroform. It contained no nitrogen did not reduce Fehling's solution and was unsaturated. There were about from four to five grammes of this

The lead sulphide precipitate was extracted with ether and alcohol. These extracts yielded small deposits of crystalline matter but for the most part dried to a red viscous substance.

The filtrate from the lead subacetate was treated with sulphuretted hydrogen the lead sulphide filtered off and the filtrate evaporated to a dark syrup which was not sweet. This syrup was treated with animal charcoal and the aqueous extract was evaporated. A syrup was obtained which on standing for some weeks deposited crystals. These were filtered on the pump and recrystallised from dilute alcohol. The mother liquor on evaporation left a syrup.

As soon as a sufficient supply of the necessary material can be obtained the nature of these various bodies will be ascertained, as far as it is possible to do so

Report by Dr. Spitta and Dr. Arthur Latham

In these experiments the aqueous solution made by Messrs Bell and Co was used The extract was not wholly dissolved, consequently the suspended matter was thoroughly shaken up before the injections were made. Guinea pigs were the animals employed.

The difficulty experienced at the outset of the investigations in obtaining really virulent cultures of tubercle bacilli was overcome by employing the caseous glands—pounded up in sterile normal saline—of guinea pigs which had been inoculated with fresh tuberculous sputum These emulsions which microscopically were very rich in tubercle bacilli were employed in each series of experiments.

Series I.

The following Experiments were made to ascertain the Lethal Dose of Lachnanthes.

Guinea-pig	Inoculation	Result.	
No 1	1 cubic centimetre of the aqueous solution	Intra-peritoneal injections	No effect
2	2 cubic centimetres	"	
3	3		"
4	4	"	"
5	5	Death in 48 hours	
6	6	24	
7	8	12	

Symptoms—There was paralysis of the hind limbs, then of both the anterior and posterior extremities, with twitching of the muscles and spasmodic movements of the limbs. The animals were unable to stand and they fell on their sides. The muscles of the jaw were affected and there was twitching

Post-mortem examination.—There was no hæmorrhage in the spinal cord. The gall bladder was full. The peritoneum contained granules of pigment and the omentum was deeply pigmented. The phagocytes contained granules of pigment. (N B.—This pigment represents the insoluble material deposited at the bottom of the bottle containing the extract.)

Series II.

Control Animals Inoculated with Tuberculous Material

Guinea pig	Weight in grammes.	Inoculation.	Result.
No 1	200	Inoculated subcutaneously at the knee with 0·5 cubic centimetre of emulsion in normal sterile saline of caseous glands of a guinea pig dead from typical tuberculosis.	Death in six weeks from typical tuberculosis
2	276	The same	Death in seven weeks and two days from typical tuberculosis.
		Animals Inoculated with Tuberculous Material and Lachnanthes.	
No 3	261	The same plus three cubic centimetres of the solution of lachnanthes injected subcutaneously at the knee on the opposite side.	Death in five weeks and two days Typical tuberculosis.
4	268	The same	Death in six weeks and one day Typical tuberculosis
5	251	0·5 cubic centimetre of emulsion of bacillus tuberculosis as above. One cubic centimetre of the solution of lachnanthes was injected twice a week subcutaneously till death.	Death in 10 days Nothing was found post mortem save enlargement of the inguinal glands and deep lumbar gland on the side inoculated with tubercle bacilli
6	250	The same.	Death in four weeks and four days. Typical tuberculosis.

Series III

Control Animals Inoculated with Tuberculous Material on May 23rd 1902

Guinea pig	Inoculation	Result
No. 1	Inoculated with 0·5 cubic centimetre of emulsion of the glands from guinea pig No 1 in Series II in normal saline.	Death in five weeks and two days from typical tuberculosis
2	The same.	Death in four weeks and three days from typical tuberculosis
	Animals Inoculated with Tuberculous Material and Lachnanthes	
No 3	The same plus three cubic centimetres of solution of lachnanthes injected subcutaneously on the opposite site at the knee.	Death in five weeks and two days from typical tuberculosis
4	The same.	This animal was lost at the Jenner Institute.
5	0·5 cubic centimetre of emulsion of bacillus tuberculosis as above One cubic centimetre of solution of lachnanthes was injected subcutaneously twice a week	Death in 19 days. Post mortem the inguinal and deep lumbar glands were enlarged on the inoculated side The spleen was enlarged and studded with nodules. Tubercle bacilli were found The retro-hepatic gland was enlarged Neither liver nor lung was infected The glands on the opposite side were not enlarged
6	The same.	Death in 25 days. Post mortem there was enlargement of the inguinal and the deep lumbar glands on the inoculated side. The spleen was enlarged and studded with nodules Tubercle bacilli were found. The liver was infected; a few small scattered nodules were present The retro-hepatic gland was enlarged and hard No lung infection was seen There was no glandular enlargement on the uninoculated side

Conclusions—It would appear from the above that lachnanthes consists largely of a resinous substance or substances and some body which is precipitated by lead subacetate and is soluble in water Further so small a dose as five cubic centimetres of an aqueous solution of the material obtained by alcoholic extraction of the plant is sufficiently powerful to kill guinea pigs, whilst doses varying from one cubic centimetre to three cubic centimetres of the same solution do not exert any inhibitory action upon the progress of tuberculosis but rather seem to hasten it. Further experiments are being made and will eventually be published.

Medical Men and Cricket—A cricket match was played at Exeter on July 2nd between Doctors" and the Exeter Home Team" which resulted in an easy win for the medical men, who scored 204 runs against their opponents 47

LEUCOCYTOSIS IN APPENDICITIS

By C J NEPEAN LONGRIDGE, M D, CH B VICT, M R C S ENG, L R C P LOND,
SENIOR HOUSE PHYSICIAN TO ST GEORGE'S HOSPITAL.

HÆMATOLOGICAL examination as an aid to diagnosis and a guide to the suitable season for operation in cases of abdominal inflammation is beginning to be held in some repute in this country The method need not be described, it may, however, be mentioned that the counts recorded in the accompanying table were taken with a Thoma Zeiss hæmocytometer, and the differential counts were made by means of films stained with Jenner's fluid The results point to much the same conclusions as have been arrived at by Cabot, da Costa, Joy and Wright, and other investigators

It is not claimed that the leucocyte count will give an absolute and infallible indication of the presence or absence of pus Such an indication is not of the *most* vital importance since pus *per se* does not kill But the question as to whether a morbid process is of increasing virulence or not hardly needs to have its importance pointed out. It is considered that in the leucocyte count we have a means to answer this important question, for a progressive increase

TABLE SHOWING THE RESULTS OF HÆMATOLOGICAL EXAMINATIONS IN CASES OF APPENDICITIS

No	Date	Age	Sex	Corpuscles Red.	Corpuscles White	Polymorphonuclear cells	Lymphocytes	Hyaline	Eosinophile	Remarks

in the number of leucocytes may be taken as evidence that the inflammatory lesion is developing in severity and may be reaching the stage of pus formation.

Perhaps of even more importance than the quantitative count is the qualitative count of the leucocytes, since it is found that in almost every case the polymorphonuclear cells are increased out of proportion to the other elements, and this fact alone, apart from any great increase in the absolute number of leucocytes, is of the greatest significance

There may be no leucocytosis in cases of appendicitis under the following conditions (1) the mild catarrhal variety, (2) fulminating appendicitis where the resistance of the patient is too feeble to react to the toxæmia, and (3) where an abscess is of some standing and is thoroughly walled off.

A CASE OF EXCISION OF CHRONIC GASTRIC ULCER

BY THOMAS H. KELLOCK, F R C S. ENG

ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN GREAT ORMOND-STREET W C.

THE following case seems worth recording showing as it does how much in a suitable case surgery has to offer to a patient suffering from chronic gastric ulcer which whilst not actually endangering life from hæmorrhage may be sufficient from the symptoms it causes to make the patient s life one of very considerable misery and suffering

In October 1901, I was asked by Dr C. T Aveling of Stamford Hill to see a patient under his care who gave the following history She was 36 years of age, she had been married for 12 years but had had no children With the exception of measles when quite young she had had no illness until the present one which began when she was 17 years old, since when she had always suffered from what she described as "chronic dyspepsia" with severe pain in the epigastrium and back *after taking food.* She had always had to be very careful in her diet and to take very small quantities of food at a time, otherwise the pain was rendered very acute. Certain forms of food she had had to avoid altogether as she knew from experience that they would bring on an attack of pain Up to the age of 24 years she was fairly plump but from that time onwards she had lost flesh considerably Since 1898 the symptoms had become worse and she had been constantly laid up the attacks of pain became more frequent, accompanied by vomiting and this independently of the ingestion of food. So suddenly did these attacks occur that frequently she had been sick in the street and had avoided going out for that reason On one occasion, whilst engaged in active housework, she vomited suddenly and thought that there were a few streaks of blood in the matter which she brought up apart from this doubtful occasion there had been no hæmatemesis at any time. The bowels had generally been constipated the catamenia regular.

The patient first came under Dr Aveling s care in 1898, the symptoms then indicating gastritis. Under treatment by medicine and dieting she improved for a time, but in July 1901, she was again under treatment gastric ulcer being suspected she then had tenderness over one particular spot at the epigastrium. The usual treatment brought about no improvement although she dieted herself most carefully With rest in bed and a nearly dry diet she improved a little but relapsed directly she got about again. The patient was a small, anæmic, very thin woman weighing 5 stones 11 pounds Her face was thin and drawn and she complained of a feeling of great weakness. The abdominal walls were thin and retracted. A little tenderness was found on deep palpation over the region of the stomach but there was no evidence of other visceral disease. She and her friends were anxious that an attempt should be made to relieve the condition by operation as although treatment by medicine and dieting had somewhat relieved the attacks of pain, her general condition was becoming worse.

On Oct. 16th, at the Clapton Nursing Home, after suitable preparation in the way of dieting the abdomen was opened through the upper part of the left rectus muscle The anterior wall of the stomach when exposed appeared to be quite healthy but what almost immediately attracted notice was a V shaped opening in the lesser omentum and directly behind this a single round hard band which was attached by one end to the hepatic part of the lesser omentum and by the other to a hard depressed spot in the posterior wall of the stomach near the cardiac end of the lesser curvature This was ligatured and divided, the upper end retracting considerably on section. On examining the stomach no sign of disease except the hard spot just mentioned could be detected by inspection or palpation and it was found possible to draw this part forwards through the opening in the lesser omentum This having been done three temporary sutures were passed through the serous and muscular coats to hold the stomach forwards, and after packing all round with sterilised gauze, the indurated part was excised by two curved incisions made one on either side of it through what appeared to be soft, healthy stomach wall. The stomach was found to be quite empty nothing escaping when it was opened. A little bleeding from the cut edges was arrested by pressure forceps and the opening was closed by three layers of silk sutures—the first in the mucous membrane only the second in the muscular coats and a third in Lembert s fashion in the serous coat, turning in a fair margin on either side and ex*tending a little way beyond either end of the incision* After cleansing the exposed part of the stomach it was returned and the wound in the parietes completely closed. The patient was rather collapsed and retched a good deal just as the operation was concluded 10 ounces of hot saline solution were injected into the rectum and the collapse soon passed off. On examining the part of the stomach wall removed it was found to comprise the whole of a circular ulcer about half an inch in diameter surrounded by a hard turned in edge. The floor of the ulcer was hard and scar like, the tissue composing it appearing to be continuous with what was left attached of the adhesion. The induration around the ulcer spread a very short distance the cut edges being soft and apparently quite healthy

The subsequent history of the case was satisfactorily uneventful Rectal feeding exclusively was employed for seven days after which it was gradually discontinued and food by the mouth was substituted. The abdominal wound gave no trouble it was healed and the stitches were removed on the eleventh day The patient complained on a few occasions of a sharp pain in the left side on attempting to move, but at the end of three weeks she was getting up walking a little and taking a fair amount of solid food without pain or discomfort In April 1902 (five months after the operation) the report of her condition was

Weight, 7 stones 13 pounds [i.e. she had gained 2 stones 2 pounds] has had no medicine for two months, can walk five miles at a stretch has no pain, can eat any ordinary food and is better than she has been for years.

A few points in the case seem worthy of remark. It is unlikely that many would be found lending themselves so readily to radical treatment and on commencing the operation I hardly hoped to find a state of things so easily dealt with. The explanation of the opening in the lesser omentum and the dense band of adhesion behind it was probably that at some time the ulcer had actually or almost, perforated all the coats of the stomach and become adherent to the lesser omentum and that the movements of the stomach had drawn that part of the omentum to which it had become attached away from the rest of that structure and so had formed the cord like process found at the operation. It is possible that the tension in this tight band had been the cause of the pain and vomiting which were set up on any movements of the stomach and when this was found the question naturally arose in my mind whether it would be sufficient to ligature and to divide it and then simply to invert the wall of the stomach round the indurated part in the hope that the ulcer would subsequently heal, and so to avoid the more serious part of the operation—the opening of the stomach itself The absence, however of any evidence of affection of any other part of the stomach and the limitation of the induration to the immediate neighbourhood of the ulcer as shown by palpation seemed sufficient justification for the more radical course which was adopted

I am indebted to Dr Aveling for the notes of the case before operation and the report of the condition of the patient in April, 1902. To his care after the operation and to the assiduous attention received in the nursing home the patient owes much of the satisfactory issue.

Queen Anne-street W

THE TREATMENT OF EARLY MENTAL CASES

BY F S TOOGOOD, M.D LOND ,
MEDICAL SUPERINTENDENT TO THE LEWISHAM INFIRMARY

THE articles by Dr Nathan Raw[1] and by Dr J W Springthorpe[2] and the able leading article in THE LANCET of June 28th, p 1842, must be my excuse, if any be needed, for again writing on this subject. Those responsible for the care of mental cases know that a very large proportion of their patients recover their mental balance within a few days under suitable treatment I do not propose to write a lengthy disquisition upon the causes of temporary insanity In the main my experience tallies with that of Dr Raw and Dr Springthorpe I have notes of several cases in which the mental aberration cleared up entirely with the removal of abdominal tumours, and many others in which restoration to bodily health coincided with the restitution of the mental equilibrium, but in my experience alcoholic excess is responsible for the great bulk of the cases of temporary insanity The ordinary cases of delirium tremens are too well known to need any comment, but there are other cases which give none of the signs of delirium tremens and yet are certainly due to alcohol. The most common class is that of a dementia varying in its degree. The patient has very little memory either for remote or for recent events He can do very little for himself , he forgets how to dress himself , he takes his clothes off and attempts to put them on again 50 times a day Unless carefully watched he passes his excretions under him, or, perhaps, urinates against the wall of the ward He does not ask for food or drink, but when supplied feeds himself in a primitive and dirty manner When asked to give an account of his doings for the day he usually details rambles into the geography of which the names of taverns conspicuously enter Usually these cases clear up within a month or six weeks There is also a class of cases which is distinctly maniacal, and another the members of which are typically melancholic

Occasionally one meets with a case in which disturbances of the special senses are met with and which are recognised as phantasies by the patient. I remember the case of a seaman who was admitted to the mental wards of St. George in the East Infirmary and whose trouble was the apparition of a female walking a few paces ahead of him and who would suddenly jump over the nearest block of warehouses. The patient was quite aware of the unreality of this apparition, but it was very life like in its appearance and persisted for weeks Disturbances of audition, taste, and smell are, of course, much more common

It was to avoid sending such cases away to asylums that I requested the justices of the peace and my board of guardians to permit me to treat all cases of insanity in the wards of the infirmary and I cannot sufficiently thank Mr Brownlow Poulter, J P , and Mr William Brown, J P and chairman of the Lewisham board of guardians, for the interest which they have taken in the experiment and for their persistent endorsement of my request for an efficient mental block.

Taking advantage of Section 21, sub section 1, of the Lunacy Act, 1890, which gives power to detain a lunatic in the wards of a workhouse for 14 days, we as a matter of routine never sent a case to an asylum until that period had elapsed. The results have been remarkable—only one third of the total number have been sent to asylums For three years these cases were treated in ordinary small wards , there were no padded rooms and mechanical restraint was very rarely necessary I do not agree with Dr Raw when he says that cases of delirium tremens cannot be certified as legally insane I have always certified them as being of unsound mind, and I have experienced no difficulty in treating them in an ordinary hospital ward We have now a separate building specially built for the treatment of mental cases, and although there are padded rooms I very rarely find it necessary to use them.

Surely, what has been done in a Poor-law infirmary can be done in a general hospital. There is an ample field amongst the non pauper classes who very properly object to a Poor-law infirmary but who would have no objection to enter the wards of a hospital. Such a course would be very beneficial to the student who, as a rule, knows nothing whatever of lunacy and has probably never seen a certificate. To the patient and his friends the advantage will be enormous two-thirds of the patients will be cured, and no stain of lunacy will rest upon the patient or his family. Those of us who work amongst the lower classes know that a person who has once been an inmate of a lunatic asylum has a very poor chance of obtaining settled employment where he is known, whilst the marrying prospects of the girls of the family are materially reduced The "stigma" of lunacy is a very real one and must be taken into consideration. The mental wards of a hospital would, of course, have to be licensed or registered and would be subject to the inspection of the Visitors in Lunacy

To the proposed reception houses of the London County Council I have the greatest objection By whatever title it may please the council to call them to the general public they will be lunatic asylums and we have no guarantee that they will be available for clinical instruction or that the medical staff will be sufficiently relieved of routine duty to enable its members to give efficient instruction The disadvantage to the student in being compelled to travel to the reception house instead of having the cases under the roof of his own medical school is too obvious to need discussion. The enormous cost might perhaps interest the ratepayer and the distance from home would be a real hardship to the patient's friends

So far as the pauper class in London is concerned the question has been met by the Poor-law authorities, mental wards having been established in all the metropolitan infirmaries , it is now for the general hospitals to deal with the cases arising in the class for which they cater

KING'S COLLEGE HOSPITAL

A CASE OF FATAL PERFORATION OF THE ŒSOPHAGUS IN A YOUNG GIRL.

(Under the care of Dr NESTOR TIRARD)

PERFORATION of the œsophagus not due to trauma or to ulceration from a malignant growth is of extreme rarity. Occasionally it results from severe vomiting, but then some predisposing cause is generally present. In the following case a possible explanation is that a bronchial gland had suppurated and burst both into the œsophagus and into the right bronchus For the notes of this case we are indebted to Dr Murray Leslie

A girl, aged 19 years, was on Nov 12th, 1901, admitted into King's College Hospital, under the care of Dr Tirard, complaining of a constant hacking cough with purulent expectoration One sister had died from tuberculosis, while the patient herself had been subject to attacks of quinsy and had had her tonsils excised She had also had some slight bronchitic attacks with a tendency to asthma as well as a slight attack of rheumatism in childhood Her present illness commenced six weeks before admission with headache and nausea but no actual sickness. A few days later she developed a cough accompanied by sickness but no expectoration The sickness had no definite relation to meals but seemed to follow the fits of coughing The patient complained at the same time of "a nasty taste in her mouth." There was no dysphagia. The cough with sickness lasted for about three weeks, but during that time there was very little expectoration. Three weeks from the onset of the first symptoms the cough began to be accompanied by a yellow and offensive expectoration. She was accordingly treated by Dr Alexander Davidson with creasote and benzoin inhalations but no improvement occurred. The cough persisted and the expectoration continued of the same offensive character She was therefore sent to the hospital for admission.

---

[1] THE LANCET, June 14th, 1902, p 1681
[2] THE LANCET, June 14th, 1902, p 1684

The patient was found to be a well-developed healthy looking girl but had a somewhat anxious and distressed aspect. There was a constant hacking cough causing great pain, especially referred to the lower part of the sternum. The cough was accompanied by the expectoration of a large quantity of yellow purulent, offensive sputum. There was no pain on deep inspiration but a catching sensation was experienced over the lower portion of the sternum. There were no definite physical signs in the chest except a few rhonchi in the right mammary region No dulness could be detected though frequent examinations were made for the purpose of detecting some localised empyema or abscess cavity The breathing was rapid—30 per minute—and thoracic in type The urine had a specific gravity of 1030 and contained a small quantity of albumin, there was a large deposit of brick red urates, there was no sugar or blood.

The constant hacking cough continued unabated and greatly interfered with the patient s rest at night she slept very badly and sometimes hardly at all. The temperature on the day of admission was 101 6° F , it rose two days later to 103 6° but dropped next day to 102 8° On the following morning four days after admission, a few rhonchi were heard over the right base, and those in the right mammary region were more abundant. Still no dulness could be detected, but there appeared some diminution of breath sounds above the angle of the right scapula. The expectoration was still abundant and was now of a brownish colour, very offensive and containing a large quantity of pus streaked with blood. On Nov 17th five days after admission, the right side of the chest was explored below the angle of the scapula but no fluid was found. The patient continued *in statu quo* for the next few days, and as the symptoms did not improve and her general condition seemed to get worse on Nov 21st the right chest was again explored, this time in front, in the mammary region A little blood stained fluid was obtained but not sufficient to indicate the presence of pleural effusion. She still complained of pain in the lower part of the sternum on coughing her cough became even more troublesome and she had very little sleep at night. The expectoration continued abundant, of a yellowish brown colour, with a good deal of whitish froth and having the same offensive character There were still some diminished breath sounds close to the angle of the scapula and impairment of the percussion note at the extreme right base, the rhonchi had now almost completely disappeared. There was continuous pyrexia, varying between 100° and 101 2° and gradually rising until Nov 25th, when the temperature reached 103° On the 26th the right base was again explored in the ninth space below the angle of the scapula, but again with a negative result. On the 28th the patient did not appear to be nearly so well the pulse was rapid though the temperature had slightly fallen and was now 101° She had relapsed into a weak asthenic condition the cough continued to be extremely troublesome with accompanying pain in the right chest, most marked above the right costal margin There was still abundant, thick, yellowish frothy offensive expectoration and there was also a distinct *halitus ex ore* while the patient herself still complained of a nasty taste in the mouth." The sleep continued to be much disturbed by the continuous coughing Moist râles were now distinctly audible at the right base, indicating a pneumonic condition. She got steadily worse and it was considered advisable to transfer her to the surgical side of the hospital where an operation was accordingly performed by Mr A. B. Barrow with a view of discovering a localised empyema or abscess cavity but without success, a drainage tube was introduced into the wound. The patient gradually sank and died on Nov 30th at 1 A M.

Necropsy —At the post-mortem examination an opening of the size of a No. 8 catheter was found in the anterior wall of the œsophagus. The opening was quite round, with smooth edges, and was situated at the level of the bifurcation of the trachea and led into an abscess cavity in the mediastinum. This cavity was of about the size of a hen s egg and lay behind the end of the trachea and the two bronchi. Its walls were ragged and grey and it exuded a gangrenous odour, in the cavity there lay a large greyish white mass of varying consistency soft in some places and harder in others. It appeared to form a kind of cone composed partly of necrotic tissue and partly of old fibrin. In the right bronchus, about one inch from the bifurcation, there was an aperture which led into the gangrenous cavity above described. The edges of this opening gave way on being touched, so that its exact size could not be estimated. The right bronchus and its branches were acutely inflamed and were filled with pus and the lower lobe of the right lung was solid and showed abundant large yellowish red areas which would soon have suppurated, there was, in fact, a condition of insufflation pneumonia. The right pleura was covered with lymph and a drainage tube was found there. There was no effusion in the pleural cavity serous or purulent, nor yet between the lobes of the right lung On the inner side of the upper lobe of the right lung however—that is next to the mediastinum and above the right bronchus—there was found a localised collection of serum and lymph. The trachea and the bronchial tubes of the left lung were inflamed but the lung itself was not pneumonic. There was some adhesion on the mediastinal side of the pleura but there was no evidence of recent pleurisy There was no foreign body found in the gangrenous cavity and the cause of the œsophageal perforation remained undiscovered

MEXBOROUGH COTTAGE HOSPITAL

A CASE OF COMPOUND COMPLICATED COMMINUTED FRACTURE OF THE PELVIS WIRING RECOVERY

(Under the care of Mr J J HUEY and Dr B CROSSFIELD STEVENS.)

THE most frequent cause of fracture of the pelvis is a buffer accident, when a man is caught between the buffers of two railway trucks and the injury described below appears to have been inflicted somewhat similarly In cases of fractured pelvis in which there is already a wound leading down to the fracture wiring is distinctly indicated. Mr W H. Battle[1] has published a similar though less severe case in which wiring was successfully performed.

On April 10th of this year a boy aged 14 years was admitted into the Mexborough Cottage Hospital suffering from a severe injury to the left side of the pelvis. He was examined and was placed under the care of Mr Huey who asked Dr Stevens to see the patient with him It was stated that the boy was carrying lamps in a coalpit and was walking on the level just behind some tubs" filled with coal which were being drawn by horses. Other tubs" were coming down an incline behind him. The driver of the latter thinking that the wedges were in position, unhitched the horses with the result that two of the loaded tubs, becoming detached rushed down the incline caught the boy and knocked him on to the tubs in front. These moving on he fell to the ground and remembered nothing more

When Dr Stevens saw the patient on admission there was not a great amount of shock or collapse but a good deal of pain and tenderness were present over the groin, the hip and the flank. There was an incised wound three inches long in the left groin just missing the external iliac artery but laying open the inguinal canal The anterior third of the iliac crest was felt to be loose and another sharp piece of bone was threatening the skin, a blister having formed at the point of tension. On further examination with one finger in the wound the whole of the left side of the pelvis seemed to be altered and some serous fluid escaped. The sartorius muscle was torn across but the pelvic viscera were intact. It was decided to explore further under an anæsthetic.

Under chloroform the incision was extended up to a point where the anterior superior spine would normally have been It was then found that the fracture involved the true pelvis. The hip-joint was disorganised and the pubic ramus was quite loose The head of the femur was *in situ* From deep down in the pelvis a loose square-shaped piece of bone was hooked up by the finger and brought into contact with another piece of the ilium and was wired with stout copper wire to another similarly shaped piece of loose bone. Another sharp triangular piece of bone was removed. The piece of bone in the true pelvis was dangerously near wounding the bladder and the iliac vessels until it was brought up and fixed in the ilium The sartorius muscle was repaired with catgut and a fresh origin was made for it by uniting it to the insertions of the abdominal wall muscles on to the iliac crest. The psoas muscle was not damaged. The wound was thoroughly irrigated with biniodide lotion the inguinal canal was made secure, and the skin was sewn up with a continuous catgut suture. A gauze drain was left in for 24 hours.

---

[1] Transactions of the Clinical Society of London vol. xxvii., p. 229

The boy stood the operation well and the gauze was taken out on the next day The temperature kept rather high for the next 12 days, this being due mostly to a broncho pneumonia The inguinal part of the incision healed but the upper part suppurated superficially chiefly from exuberant granulations all through May and then a spicule of bone came away

Remarks by Dr STEVENS —The wound is now healed and a poroplastic pelvis and thigh splint is being worn There is good flexion of the joint and the patient can now walk a little way with all his weight on the pelvis. It is yet early to say whether he will be able to work again but the prospects are good. I should certainly recommend the expediency of wiring the fragments of a badly fractured pelvis It is remarkable that with such a smash the pelvic viscera were uninjured I am indebted to Mr Huey for allowing me to publish this case

Medical Societies.

OPHTHALMOLOGICAL SOCIETY

The Bowman Lecture

THE following is an abstract of the Bowman Lecture delivered before the Ophthalmological Society on June 13th by Professor ERNST FUCHS of Vienna. The lecture was illustrated by numerous drawings

Bowman's name, said Professor Fuchs, would be for ever connected with the development of anatomy physiology, and ophthalmology, and as far as the eye was concerned Bowman's membrane and Bowman's tubes would perpetuate for all time his name in the memory of the student of medicine. In discussing keratitis the lecturer declared his intention of confining himself to the consideration of recent disease, showing what anatomical changes corresponded with visible signs, such as opacity, loss of brilliancy, &c. The transparency of the cornea allowed a closer comparison between clinical and microscopical appearances in this than in any other structure, especially with the aid of a lens or corneal microscope Diffuse opacity would be found to correspond with an infinite number of minute grey points representing swollen corneal corpuscles, aggregated lymph cells beside them, or accumulations of corneal corpuscles in lymph spaces. The surface from being smooth and brilliant became dull and stippled at the slightest disturbance of underlying tissues corresponding with a change in the epithelial layer In the normal structure the nutrition of the epithelial layer was provided for by osmosis from the corneal tissue through Bowman's membrane, and the regeneration of cells by division of the basement and middle layers In health this was slow, as evidenced by the scarcity of dividing nuclei On account of the exposed position of the corneal epithelium its pliant, delicate nature, and its loose attachment to subjacent structures, abrasions were common, and rapid and extensive exfoliation took place in inflammation Its vitality was further lowered by the low temperature resulting from surface evaporation and its dependence for nutrition on non vascular tissues. Its sensibility was its chief defence and the integrity of the epithelium was the chief defensive agent against the intrusion of microbes The close and persistent growth of these surface cells tended to level all irregularities, producing a thicker layer where there was loss of substance and a thinner one over any protrusion This was illustrated by drawings, as was also the rapid development of these cells preventing direct union of the tissues after a cataract extraction of four days' standing, having already penetrated the wound as far as Descemet's membrane. A drawing was shown illustrating a still further development in which the superficial corneal epithelium had penetrated to and lined the entire anterior chamber, covering both the iris and back of the cornea, this drawing was from a cataract extraction of several years' standing This condition practically represented cyst of the anterior chamber, the tension was raised Four such cases had come under the lecturer's observation and he suggested that this might be the explanation of increased tension after cataract extraction where there was no other cause of glaucoma There also occurred small epithelial cysts in the root of the iris continuous with the surface epithelium and representing the blind end of its invagination These would in time develop into iris cysts and were, except in distribution, analogous to the chamber cyst just mentioned Cysts of the iris occurring after penetrating wounds were always due to this kind of intrusion of the external epithelium Another instance of this intruding tendency was furnished by cases of old leucoma, in such cicatricial tissue there often occurred calcareous deposits which consolidated into calcareous plates. These, at first intimately connected with the contiguous tissue, presently separated from it by shrinkage and lay in it like a foreign body A drawing showed the surface epithelium penetrating to this space, surrounding the plate, and effecting its separation Another drawing showed the process nearly complete, the epithelium on the outer aspect having necrosed, while on the deep surface it separated the mass from the living connective tissue, thus at the same time protecting the eye from external agencies by a continuous epithelial layer The vital energy of this epithelium was greater at the periphery in proximity to the nutrient vessels When uniformly affected it was speedily thrown off in the centre but grew exuberantly at the margin, as in kerato-malacia and neuro paralytic keratitis, and most strikingly in marginal ulcers where the epithelium was seen to push quickly towards the bottom of the ulcer peripherally, whereas the central margin remained bare and infiltrated On this account many ulcers tended to progress 'towards the centre but not towards the margin as in fascicular keratitis Disturbance showed itself by dulness (unevenness) or haziness (opacity) of the epithelium, where the epithelium was raised in places the small vesicles appeared black if the subjacent cornea was clear The opacity was due to abnormal fluid either between or within the cells It commonly occurred between the cells in glaucoma (œdema of epithelial layer), separating first the basement and then the superficial cells, and might form vesicles A figure from Greeff showed this and swelling of cells from imbibition of fluid. The cells might burst and leave depressions while the swollen ones projected, thus producing an uneven surface The stippled appearance in glaucoma, irido-cyclitis, and interstitial keratitis was thus accounted for The entire layer might be affected, producing a homogeneous mass which separated. Absorption occurred quickly, even within 30 minutes, under eserine The superficial cells separated and fell off In neuro paralytic keratitis the desquamation was specially rapid, being due largely to exsiccation, but it occurred from nerve changes in man where this was prevented The change occurred principally in the centre while there was proliferation at the margin, the cornea being left uneven with a stippled appearance Only the basement layer might be left and the cells altered in shape, being long, short, or oblique, or the loss might be total, as in conjunctivitis and inflammation of other mucous membranes (desquamative catarrh) This condition endangered the cornea by facilitating the entrance of micro-organisms and conjunctival disease was often followed by corneal disorder Change in the epithelium was the cause of such disorders of vision as coloured halos round lights, as in glaucoma and cocaine instillation, especially where this had been long continued or the eye had been left exposed The epithelium became opaque and dull and desquamated The lecturer never entrusted patients with cocaine particularly when suffering from keratitis Thinning of the epithelial layer occurred from pressure of the lid, the surface remaining smooth, as it did in atrophy from insufficient nutrition, the number and size of the cells being diminished Where calcareous deposits occurred in corneal cicatrices bacteria might invade the cornea, causing necrosis This was the explanation of the rapidly destructive ulcers in old leucomas (atheromatous ulcer, sequestering cicatricial keratitis) resulting in perforation and panophthalmitis This might also occur from within, as in corneal degeneration Local areas of the kind resulted from irritation or might develop after cataract extraction, producing inflammatory areas with lymph cells which might ulcerate or disappear Exsiccation if super ficial produced opacity if deep xerotic keratitis To sum up the causes of these superficial changes, they might be due to conjunctival disease causing damage by secretion —e.g gonorrhœal ophthalmia deeper tissues as in glaucoma, irido-cyclitis, panophthalmitis, through alterations in pressure circulation, and quality of lymph, or degenerative changes in the cornea which varied much with the stage and malignancy of the pathological process. The dotted appearance in keratitis as seen with a lens differed from the haziness due to changes in the media or deposit of fibrin at the back of the cornea which always appeared uniform, this appearance in the cornea being only produced by the imbibition of fluid Striated keratitis was due to swelling (after cataract extraction) producing folds at the posterior surface of the cornea. Swollen tissue on the surface might be clear and free from ulceration though necrotic The bluish swelling in newly born children and in glaucoma were probably due to imbibition. The slow changes in old men (after 60 years of age) senile sclerosis, which produced ultimate blindness, were due to abnormal liquid in the cornea which impeded the lymph flow It was probably due to a change in the general nutrition or to increased permeation of the aqueous humour into the cornea. A change in the epithelium was superadded and the slow affection of both eyes suggested some general agent. A uniform infiltration of the cornea with lymph cells produced a uniform opacity An injurious agent in the aqueous humour as in commencing panophthalmitis or irido-cyclitis, caused increased circulation at the margin two currents of lymph cells emanating from the vessels of the limbus and the anterior ciliary vessels which resulted in an annular thickening The entire cornea might be affected from a wound or ulcer the change clearing up concentrating or becoming marginal In the latter case a ring shaped thickening due to infiltration 1 5 millimetres in width and about this distance from the limbus occurred and was a rare consequence of ulcer or panophthalmitis.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY

Copper Test for Sugar in Urine —Nerve Regeneration.— Jejunal Fistula —Exhibition of Cases and Specimens

A MEETING of this society was held on July 2nd Sir THOMAS R. FRASER, the President, being in the chair

Dr T S. CLOUSTON in the name of the members present, congratulated the President on the honour of knighthood which had been conferred on him by the King —A letter from Professor Huchard of Paris was read thanking the society for his election as a corresponding member

Dr F D BOYD read a paper on the Fallacies of the Copper Reduction Test for Sugar in the Urine. It dealt with the substances apart from glucose which though they might have no known pathological significance yet had the power on the application of Trommer's or Fehling's test of dissolving copper hydroxide and subsequently reducing it on the application of heat with the formation of the red suboxide. A number of such urines had come under notice. In making the observation two cubic centimetres of Fehling's solution were taken as an average quantity used in the routine application of the test and titrated with a solution of the different substances of known strength. Of those substances the most important were the glycuronic compounds which might appear in the urine in apparent health after the administration of drugs and in infectious conditions They could be estimated by the benzoyl-chloride method, for recognition of their presence in small quantities the phenyl hydrazin bromide test and the orcin and phloroglucin tests were used. The importance of the recognition of the glycuronic compounds was illustrated by the case of a middle-aged man who was desirous of increasing his life assurance policy, but when examined he was at first rejected on the supposition that his urine contained sugar On subsequent more careful examination the urine was found to be clear and of a normal specific gravity with the copper and bismuth tests there was decided reduction but the fermentation test was negative and no crystallised osazon was obtained with phenyl hydrazin. The copper reduction was therefore due not to sugar but to a glycuronic compound The life was accepted for insurance and the applicant was still, after eight years in excellent health. Creatinin had not a powerful copper reducing effect. It required 0·07 gramme creatinin to have an appreciable effect in reducing two cubic centimetres of Fehling's solution. 1 5 cubic centimetres of urine contained normally about 0 0001 gramme creatinin. It was therefore concluded that creatinin could be neglected. With uric acid 0 017 gramme gave a decided reduction in two cubic centimetres of Fehling's solution while 0 03 gramme gave complete reduction. Normally 1 5 cubic centimetres of urine would contain less than 0 0001 gramme uric acid—a quantity too small to produce any appreciable reduction in two cubic centimetres of Fehling's solution. Uric acid could therefore be neglected as a fallacy of the copper reduction test unless present in excessive amount in a highly concentrated urine and even then the fallacy was improbable. Alkaptonuria was next referred to a condition due to the presence of pyrocatechin uroleucic and homogentisic acids, and the allied condition carboluria. The occurrence of alkaptonuria was of importance not so much from any pathological significance which it was known to possess as from its liability to be mistaken for glycosuria from its decided copper reducing power Pyrocatechin was found to have an active influence upon Fehling s solution If two cubic centimetres of Fehling s solution were treated with 0 01 gramme pyrocatechin a deep green colour resulted, while 0 02 gramme gave a porter colour with distinct copper reduction. Hydrochinon which appeared in the urine as an ethereal sulphate showed a deep brown colour with Fehling's solution 0 00125 gramme gave a distinct reduction Dr Boyd said that liability to error would be greatly diminished if the tests were made at a temperature below the boiling point. Glucose gave reduction below the boiling point, while the other substances gave no distinct reduction and if doubt remained the phenyl hydrazin the phenyl hydrazin bromide and the fermentation tests provided easy means of distinguishing the reducing body

Dr R. A. FLEMING read a paper entitled On the Peripheral Theory of Nerve Regeneration with special reference to Peripheral Neuritis. He said that there were two theories of the nerve regeneration which took place when a peripheral nerve was divided. According to the central theory the peripheral end could only regenerate by the central axis cylinders growing down into it while according to the peripheral theory regeneration could and did occur in the peripheral end even when reunion of the two ends never occurred. The central theory was the old theory almost universally held until quite recently The peripheral theory of regeneration was by no means of recent inception but the work of Kennedy and more recently of Mr C A. Ballance and Dr Purves Stewart had done much to direct attention to it in this country Dr Fleming demonstrated neuroblastic regeneration in the peripheral ends of rabbits nerves at various periods after complete division and referred to the value of Stroebe s method of staining axis cylinders. He adhered to the belief that the central axis cylinders were not purely passive agents in the work of regeneration of a nerve after division and stated various facts which appeared to him to point to the probability of this combination of the central and peripheral theories of regeneration being correct. The evidence obtained from a study of a number of amputation neuromata appeared to support this view He then referred to four cases of peripheral alcoholic neuritis in all of which regeneration had occurred in some of the affected nerves The fact that the neurilemma nuclei appeared to have a trophic influence towards the portion of axis cylinder between the two nodes of Ranvier suggested that the neurilemma cells might act as neuroblasts even without considering the much stronger and more logical evidence from embryology This trophic function of neurilemma Dr Fleming described some years ago Neuroblastic" regeneration was probably not an obvious process in normal nerves for the truth of this statement Dr Fleming deduced evidence from the examination of nerves in a small number of cases presumably healthy so far as the nervous system was concerned. There was no regeneration similar to that seen in the four cases of peripheral neuritis described Neuroblastic" regeneration was nature s attempt at repairing the damaged nerve-fibres in peripheral neuritis and it seemed to be the only possible explanation of recovery in a severe case of the disease in which long areas of nerve-fibres had suffered. Dr Fleming suggested that the peripheral axis cylinders were probably of epiblastic origin.

Dr HENRY M CHURCH read a paper on a case of Jejunal Fistula. He said that although many cases of intestinal fistulæ had been recorded few were associated with the jejunum. Mr Golding-Bird's case, published in the Transactions of the Clinical Society in November, 1885, was then shortly described This patient lived only nine days after the operation. His food was passed directly into the jejunum and on several occasions he suffered from severe attacks of indigestion which followed a fluid meal of from 15 to 20 fluid ounces These attacks only ceased on diminishing the quantity of food injected In the following case food was administered solely by the mouth, some of it being discharged by the jejunal fistula and giving the patient great distress, while some of it passed on into the bowel. The patient was a woman, aged 46 years, who underwent operation for acute obstruction of the bowel in 1884 and died in 1892 During this time she had a fistula in connexion with the upper part of the bowel and suffered great misery from this, and especially from the digestive action on the skin due to the constant outflow of pancreatic and biliary secretions. The fluid which issued from the fistula was generally clear, like water and odourless, but not of the slimy, syrupy character ascribed to the pancreatic secretion. Occasionally, there was a flow of green bile which, like the other, caused a burning pain about the wound Over a large area round about there was acute inflammation of the skin. The position of the opening a little above the umbilicus, together with the character and time of the discharge, seemed to locate it as jejunal Morphia was of the greatest value to this patient, it dried up her wound, raised her spirits, and induced sleep Even when it did not dry up the wound it seemed not only to diminish sensibility but actually to deprive the pancreatic discharge of its irritating properties, as evidenced by its diminished action on the skin In large or even in moderate doses it lessened peristalsis and caused constipation. It also inhibited salivary and pancreatic section and induced great dryness of the mouth She feared to drink water to allay the thirst knowing the painful consequence of the increased gastric and intestinal flow which ensued. This seemed to point to the probability of water not being absorbed in the stomach. Headache was generally relieved by taking from three to five grains of citrate of caffeine This drug always greatly increased the flow from the fistula as well as the salivary secretion. In most points caffeine seemed antagonistic to morphia. In whatever form given alcohol always increased the flow and irritated the wound and also stimulated the salivary secretion. In small doses rhubarb always stopped the discharge for from three to four hours, and then the drug came away through the wound and could be both seen and smelt. It irritated the wound much and this was probably due to the chrysophanic acid in the rhubarb However, the drug improved both the appetite and the general condition of the patient. Rhubarb was a sialogogue and so it was difficult to understand how it dried up the wound for so many hours, for with the exception of this drug it was always noticed that any stimulant of salivary secretion was invariably associated with an increase of discharge from the fistula. Before reaching the wound the powerfully astringent influence of the rheotannic acid must have come into play Castor oil was often taken as an aperient but a large proportion of it emerged from the fistula in from one and a half to two hours. It was quite unirritating to the wound but increased the flow from it. This was the only aperient which did not give pain to the wound. The stools always indicated that all the digestive ferments had been at work. Enemata had always the effect of increasing the flow from the fistula for many hours and if castor oil were added to the enema globules of oil were seen to emerge copiously from the fistula some hours afterwards. There seemed to be a complete antiperistalsis on these occasions. Emotion always increased the flow from the wound as also did cold weather As regards food years of observation showed that foods rich in proteid substances were best suited to her For years white meat pounded to a cream and mixed with bread crumbs was administered warm from every three to four hours. Vegetable diet always occasioned pain and however cooked was undigested and came through the fistula with a specially hot and painful discharge which caused not only the margins of the wound but also the surrounding skin to bleed. The only agent which relieved the irritation of the skin was tannic acid frequently applied in weak solution and as an ointment.

Dr CHALMERS WATSON showed a girl, aged who had suffered from Lupus on the Left Cheek four or five years There was a pronounced fami tuberculosis. The treatment consisted in the lo tion of a product of bone marrow (myelocine) crusts had been bathed off this was applied d May 23rd) Already there was a distinct impro the condition and the patch was beginning to happens in the "light" treatment of this disease.

Mr ROBERT PURVES showed a case in which th Artery had been Ruptured by Constriction of the T Running Rope, the torn end of the artery being s natural method of arrest of hæmorrhage.

Mr ALEXIS THOMSON showed a Depressed Fractu Skull sustained 20 years before death

Reviews and Notices of Books

An Introduction to the Bacteriological Examinati Water By W H. HORROCKS, M B, B Sc. London J & A. Churchill. 1901. Pp 300 10s 6d

IN this work Dr Horrocks has made a very valuable tribution to our knowledge not only of water bacteri general but also of pathogenic bacteria which gain water supplies in particular His views as to the most cient methods of conducting the bacteriological examinatio of water are based on practical researches In this his own experiments at Netley relating to the duration life of the typhoid bacillus in water and sewage are greatest importance and interest. Taking these in conjunction with those of other workers it seems extremely probable, he says, that under natural condi tions comparatively few typhoid bacilli will gain access to a water-supply, and in order to detect them it will be necessary to examine a considerable quantity of the water Unless the specific pollution is continuous it is extremely unlikely that typhoid bacilli will be detected in a water-supply if more than a week has elapsed since the actual pollution has occurred. This view had able support in the circumstances of the outbreak of fever at Maidstone Ten days after the specific infection had taken place a bacteriological examination of the infected water failed to find the typhoid bacillus, though the presence of the bacillus coli showed that sewage contamination had occurred. It will be remembered that in the case of Worthing it was thought that the typhoid bacillus had been identified, but Dr Horrocks states that the given then as indicating the presence of the typhoid bacillus would be considered at the present day as quite insufficient to establish the diagnosis of this organism, consequently, he adds, the Worthing epidemic must be relegated to the large class of cases in is still a doubt as to the presence of the bacillus typhosus in the water supply He next asks the question whether, apart from the isolation of the bacillus typhosus, there are any means of diagnosing pollution of a water supply by the specific dejecta of cases of enteric fever To some extent, as he shows, there are, for in some experiments which he made the varieties of the bacillus coli isolated from typhoid dejecta proved to show much greater sensibility to agglutination than did the varieties of the bacillus coli found in normal stools. Therefore, if cultures of the bacillus isolated from suspected water supplies are found to come within the typhoid range of agglutination there is some reason for assuming that the water-supply in question has been polluted with typhoid dejecta This is but one example of Dr Horrook's earnest attempt to place the bacteriological examination of water upon a satisfactory basis and in other chapters he indicates the value of other organisms as a ntamination He, with others, has carefully studied the cteriflora of sewage sufficiently to enable certain bacteria be classed as normal inhabitants of sewage The book is luable, therefore, as being largely the outcome of a series his own painstaking researches the results of which e of the utmost importance and should prove of extreme rvice to the water bacteriologist.

---

ncyclopædia Medica Under the general editorship of D CHALMERS WATSON M B F R.C.P Edin Vol. X. Pregnancy to Scarlet Fever Edinburgh William Green and Sons. 1902. Pp 516. Price 20s

THE subject of pregnancy which was commenced in the eceding volume, is concluded in the present one. Under e heading ' Pathology of Pregnancy " are several contribu ons. Dr W E. Fothergill (Manchester) writes on the ffections of the Ovum and Decidua and Dr T W Eden ondon) on Diseases of the Placenta and Cord. Then llow three papers on affections and accidental com lications—Affections of the Generative Organs, by Dr Stephenson (Aberdeen) Systemic Disturbances, by r John Phillips (London), and Death during Preg ancy by Dr W E. Frost (Edinburgh), and, finally r Henry Jellett (late Master of the Rotunda Hos tal, Dublin) writes on Hæmorrhage associated with regnancy It will thus be seen that the whole subject of regnancy is considered most thoroughly and from every int of view An immense amount of information is ntained in the pages devoted to the matters above entioned which will prove most useful for reference by e medical practitioner

An elaborate account is also given of the Puerperium. The hysiology of that period is considered by Dr A E. Giles London) The changes in the maternal system are first de ribed and then directions are given as to the management f the patient up to the time of complete convalescence. he pathological section is split up into five divisions r W J Smyly (late Master of the Rotunda Hospital ublin) writes on Puerperal Infection. He gives an interest ng *résumé* of the bacteriology of the condition, laying articular stress on the germicidal powers of the vagina. he author concludes that the vagina contains germs which re harmless under normal conditions but which may some imes become dangerous in the presence of dead matter or issue the vitality of which has been reduced by crushing and ruising in prolonged and difficult labours, and which may lso be productive of harm if carried upwards into the uterus. he remarks on Affections of the Breasts and Nipples are by r J Haig Ferguson (Edinburgh) and those on Constipation nd other Disorders by Dr W Fordyce (Edinburgh) The ubject of Puerperal Insanity is dealt with by Dr G R. Vilson (Edinburgh) the clinical varieties are particularly vell described. Finally Dr Smyly describes the condition nown as ' Sarcoma Deciduo-cellulare or Deciduoma Malignum.

The article on the Pulse by Dr H. Oliphant Nicholson (Edinburgh) affords interesting reading The use of the phygmograph is minutely described but we cannot agree with the author in his statement that the only accurate method of recording the pulse is by means of that instrument. It is true that as a means of procuring records its alue is very great, but we believe that most physicians would prefer to trust to the sensations transferred to the ingers by actually feeling the pulse rather than to an xamination of a sphygmogram For theoretical purposes the sphygmograph is of the utmost use but we are doubtful if the same worth can be attached to it for clinical work.

Another contribution worthy of notice is that on Diseases of the Rectum by Mr H. W Allingham (London). We may especially draw attention to his remarks on hæmorrhoids. The operative procedures are fully described and stress is laid on the after treatment and the complications that may follow operation for hæmorrhoids.

Those practitioners who interest themselves in ophthalmic work will find a large amount of information in the article on the Retina and Optic Nerve by Mr R. Marcus Gunn (London) A full account is given of inflammation and atrophy of the nerve the injuries to which it is liable, and the tumours with which it may be affected. The diseases of the retina are also considered, the various forms of retinitis being ably described

The subject of Acute Rheumatism receives its due amount of notice from Dr F J Poynton (London) He acknowledges rheumatic fever to be an infective disease but as the result of his researches in association with Dr Alexander Paine (London) he believes that one and not several different bacteria will prove to be the true excitant of the disease. Although there are strong reasons for believing the cause of rheumatic fever to be an infection with a diplococcus which has been isolated by several observers this can only explain one factor in the disease—the exciting cause. As Dr Poynton remarks, the peculiar poisons that are formed and the peculiar vital chemistry of the human tissues are as yet unknown. The article on Chronic Rheumatism is by the editor (Dr Chalmers Watson) and that on Rheumatoid Arthritis by Dr Julia Cook (London) who publishes some good reproductions of photographs illustrating the joint affections and discusses the pathology in a full and interesting manner

Amongst other contributions to this volume we may mention the following Psoriasis, by Dr H. Radcliffe Crocker (London), Puberty by Dr Garrett Anderson (London) Quarantine, by Dr W Collingridge (London) Raynaud s Disease, by Dr J Purves Stewart (London), and Rickets, by Dr H. Ashby (Manchester).

A Practical Treatise on Small pox Illustrated by Coloured Photographs from Life. By GEORGE HENRY FOX, A.M. M D Consulting Dermatologist to the Health Department of New York City with the collaboration of S. D HUBBARD M.D S POLLITZER, M D and J H. HUDDLESTON M D Complete in two parts. Part I. with three Plates and eight Coloured Plates, containing 19 Illustrations. Pp 14 Part II. with three Plates and eight Coloured Plates, containing 24 Illustrations. Pp. 17 London and Philadelphia J B Lippincott Company 1902. Price 12s net.

THIS work is very conveniently adapted for practical use in the out-patient room or at the bedside. The parts are in paper covers and are unstitched the plates being loose The importance of the work lies in the illustrations These are of varying degrees of merit. Some are excellent, such as most of those depicting cases of small pox in the pustular stage. From them may be gathered a very true conception of the appearance presented by most cases of small pox in that stage of the disease. Others of the plates are not so satisfactory In some instances this is due to faults of reproduction. But in most it arises from the difficulty of obtaining in a photograph results which are due not so much to light and shade as to very delicate effects of colour We suppose, for instance that the illustrations of small pox erythema, of hæmorrhagic small pox and of the papular eruption would be of very little assistance to a novice in making a diagnosis. Unfortunately those types of small pox and stages of the disease which present most difficulty in diagnosis are the most difficult to illustrate satisfactorily We think however that something further might have been accomplished by a better selection of cases and points to be illustrated and by a more systematic attempt to represent the essential peculiarities of the disease One illustration *only* is given of chicken-pox, for instance This is from a photograph of the back of the patient's trunk. But the selection of this part of the body makes it impossible for the illustration to convey any information as to the general distribution of the eruption over the surface, while the scale of the picture and its lack of definition prevent any idea being gleaned as to the character of the lesions themselves. The illustration, in fact, would represent equally well a mild case of small pox. Some of the illustrations depicting the condition of the skin in the later stages of small pox are praiseworthy One of these, showing the inspissated pustules left in the soles of the feet, is of real value.

The letterpress is disappointing It consists of a systematic account of the clinical features, diagnosis, and treatment of small pox, without special reference to the illustrations The chapter on Diagnosis, to which the reader naturally turns, makes little attempt to set out the principles on which the diagnosis depends The author contents himself with a perfunctory *résume* of the clinical differences between small pox and the various diseases for which it is liable to be mistaken The accuracy of some of the statements made is open to question

Manual of Military Ophthalmology for the Use of Medical Officers of the Home, Indian and Colonial Services By M T YARR, F R.C S Irel , Major Royal Army Medical Corps London Cassell and Company, Limited. 1902. Small 8vo, pp 236

THE book, of course, follows the lines adopted by the authors of most modern manuals, the optical properties of the eye, the methods of testing the sharpness of vision, a description of the ophthalmoscope, and a consideration of errors of refraction occupying the first part , then follow an account of strabismus, the characters and treatment of the diseases of the eye most commonly met with in soldiers, gonorrhœal, syphilitic, malarial, and non malarial affections, trachoma, injuries of the eye, sympathetic ophthalmia, glaucoma, and cataract, and the work concludes with a chapter on Cataract. The above enumeration of the subjects which Major Yarr discusses will give an idea of what he has thought it expedient for the young military surgeon to know well at the beginning of his career and what he may safely omit, or at least learn from later experience. A knowledge of refraction is necessary and stress is rightly laid upon it, because irremediable defects of vision necessarily exclude the admission of the recruit or the officer into the service The present arbitrary limits determined by letters and dots or other tests are absurd Many a good man has been rejected who in the armies of the continent would have been unhesitatingly accepted, and we agree with Major Yarr when he says "The time is bound to come when the English, like the foreign, soldier will be permitted to wear glasses, and then comparatively high errors of refraction, if unaccompanied by disease, can be passed ' That time has, indeed, already come, for a Regulation in the Army Orders, issued by the War Office on March 1st, 1902, and noticed in our columns,[1] gives permission to wear spectacles to both officers and men The several sections of this little treatise are written with much perspicacity and intelligence, especially those dealing with injuries to the eye from gunshot wounds and from the entrance of foreign bodies into the eye. Such injuries are rare even in long wars In the American War of Rebellion only 1190 cases of gunshot wounds of the eye occurred in 408,072 cases of wounds of the body generally It will be interesting to know the proportion of wounds of the eye to general wounds in the recent war when its medical history comes to be written. The appendix contains the vision regulations of the English army compared with those of other armies Major Yarr's book will prove useful and instructive to every army surgeon

LIBRARY TABLE

Agricultural Bacteriology A Study of the Relation of Bacteria to Agriculture By H. W CONN, Ph D , Professor of Biology, Wesleyan University London Rebman, Limited. 1901 Illustrated Pp 412 Price 11s net —The present work strikes out a somewhat new line of instruction in bacteriology The class of readers for whom the book is written is not indicated by the author, but, from the absence of technicalities and the somewhat popular form of the information—popular, however, in the best sense—it would appear to be intended for the agriculturist rather than for the bacteriologist To the intelligent farmer it should prove very useful and it would be excellently adapted to the needs of the students who attend the recently established county council dairy farms and all who are interested in dairy produce, whether as producers, distributers, or consumers After a very short account of the nature and classification of bacteria the author passes to the consideration of the bacteria of soil and water, with special reference to the fixation of nitrogen from the air and the processes of denitrification and oxidation This rather difficult subject is dealt with very clearly and the limits of our knowledge are sharply distinguished from our more or less probable speculations The work of Frankland and Warrington on nitrification is rather unduly neglected and there is a misleading misprint on page 90 of "oxygen" for "nitrogen." The root nodule organisms in leguminosæ are considered at length, as is the direct fixation of nitrogen by some species of soil bacteria. The relations of bacteria to milk, butter, and cheese occupy, as might be expected, a considerable section of the work, and the treatment of the subject is marked by common sense, an appreciation of the relative importance of the various topics, and a critical examination of laboratory results in the light of practical experience Throughout there is an appreciation of the farmer's point of view We find a straightforward condemnation of all "preservatives" and on p 214 an excellent and not utopian set of rules for the dairyman , if these were conformed to they would largely check the dissemination of disease. Pasteurisation is preferred unhesitatingly to sterilisation on practical grounds Pasteurisation means, of course, centralisation of the dairy industry, but on commercial grounds there is a strong tendency in that direction Apparently in the United States the use of an artificial "starter" for ripening cream for butter making is common, though a pure culture is not invariably or even commonly used. The probable importance of enzymes in cheese ripening and in ensilage is insisted upon, though the bacteria seem to be of chief importance in the production of characteristic flavours The important question of tuberculosis and dairy products is considered in detail and with common sense. Koch's recent views are, perhaps, remembering their unfortunate practical results, treated with too much consideration The use and importance of tuberculin are pointed out, but practical instructions as to its use are wanting , this, however, belongs to the work of the veterinary surgeon and does not come within the scope of this book. At the end of each section there is usually a short epitome of the principal conclusions justified by the present state of our knowledge of the subject. This will prove of use to the reader, and the conclusions do not, as sometimes occurs in scientific papers, go beyond the warrant of previously stated facts To all interested in agriculture in its broadest sense this book may be strongly recommended.

[1] THE LANCET March 29th 1902, p. 905.

The Elements of Mind Being an Examination into the Nature of the First Division of the Elementary Substances of Life By H. JAMYN BROOKS. London Longmans Green and Co. 1902. Pp. 312. Price 10*s* 6*d* net —Mr Brooks in his dedication of this book which he calls a work says that its appearance is due to the kindly encouragement at a critical period of Professor William James and Dr J Beattie Crozier There is much internal evidence to show that Mr Brooks was pleased with his own ' work, but it was mistaken kindness—if it were kindness at all—for his friends to encourage him to publish it. Mr Brooks claims to have discovered the elements of Mind which he opines when compounded with those of Force and Matter constitute the mysterious substance which we call Life, he seems to claim to have discovered or invented the true Deity and he does not accept the atomic theory Of the making of such books there appears to be no end and much study of them is weariness to the flesh. It is also entirely unprofitable.

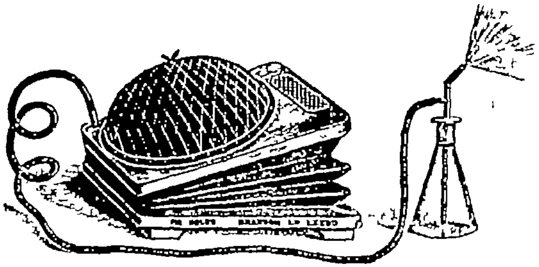
The Diagnosis of Nervous and Mental Diseases By HOWELL T PERSHING M D Professor of Nervous and Mental Diseases in the University of Denver London Rebman, Limited 1901. Illustrated. Pp 223. Price 6*s* net. — The object of this book is to facilitate the recognition nervous and mental diseases by physicians who are not specialists in those diseases. It cannot, of course, take the place of clinical instruction, but it is a useful compendium of diagnostic symptoms for the student s guidance. It deals in a clear and adequate way with the clinical examination of patients, with special reference to the nervous system—a point dealt with nowadays in nearly all text-books. The principles of cerebral localisation and their application to diagnosis are next pointed out Then follow in some detail descriptions of the signs of hysteria, hemiplegia, monoplegia, paraplegia, oculo-motor and facial paralyses, bulbar paralysis, ataxia, tremors, spasms, and contractures. The descriptions given are marked by conciseness and lucidity and the methods of differential diagnosis are very clearly indicated Much information is condensed into these few chapters. Other chapters deal with optic neuritis, trophic and vaso-motor disturbances, and the nature and distribution of pain in nervous disorders The final portion of the work is devoted to disorders of speech and the diagnosis of the various forms of insanity The work throughout is marked by clearness of description and real insight into the complex and difficult subject of diagnosis of nervous and mental diseases generally It will undoubtedly be a helpful work to the practitioner and to senior students. The printing is clear and the text is remarkably free from errors

On the Use of Roentgen Rays and other Radio-active Agencies in Surgery and Medicine By G M LOWE, M.D F R.C P Edin —This is a reprint of a paper read before the Nottingham Medico-Chirurgical Society In it Dr Lowe gives details of his method of working For power he uses either two accumulators giving 12 volts and 28 ampères or else the current from the main at a pressure of 230 volts continuous current. He uses a 10-inch Watson coil and contact-breaker for accumulator work but with the current from the main he uses two of Cox s electrolytic breaks apparently of the Mackenzie Davidson pattern Some illustrations accompany the paper one of which a photographic print of a fractured humerus, shows admirable definition.

New Inventions.

A SPRAY APPARATUS FOR DISINFECTING WITH FORMIC ALDEHYDE.

THE accompanying illustration shows a spray apparatus for the convenient application of formic aldehyde as a disinfectant. It has been introduced by Messrs. Reynolds and Branson, Limited of Leeds and is specially designed to fulfil the requirements of sanitary officers in the disinfection of houses schools and other buildings The current of air for producing the jet of spray is obtained by means of bellows worked with the foot The portable form here shown can conveniently be carried on a bicycle and in this way may be made to do duty over an extensive district. The advantage is claimed for it that it can be used from the outside of a room by passing the tube through the doorway The price of the apparatus complete in a waterproof carrier is £2 10*s* Messrs Reynolds and Branson have also devised an apparatus for utilising compressed air or oxygen, 10 cubic feet of which will they say, vaporise about half a pint of formaldehyde solution—namely a quantity sufficient for an ordinary bedroom. For working on a more extensive scale they supply a larger form of apparatus, the price of which is £6 10*s*



A NEW SCOTOMETER.

MESSRS. WEISS AND SON Limited have made for me a little instrument which in an amateur form, I have found very useful for the purpose of rapid determination of the condition of central colour disturbance common in toxic amblyopia. Behind a screen in which is cut a square aperture there rotates a disc bearing squares of red and green colour—two three, five, and seven millimetres in diameter The rotary disc has an automatic check action, so that it stops as each successive test is brought into the aperture. The observer using his nose as a convenient point of fixation, can pass the 'scotometer over it and judge the presence and extent of colour disturbance in the patient by his perception of the colour of a larger or smaller square or by the movements of a square of given size from the fixation point. The colour squares are of the greatest range and size conformable with the handiness of the instrument which is of the same size and thickness as the usual one-and a half inch trial lens so that it finds a convenient place in the ophthalmoscope pocket-case or in a slot of a trial lens case. In the actual instrument the face is clear of lettering that which appears in the figure is stamped on the back.

LONDON SATURDAY, JULY 12, 1902

The Illness of the King

WE have but little news to communicate this week with regard to His Majesty's illness, a fact which may be considered as very satisfactory, for the case is one in which in its present stage "no news" is emphatically "good news." We are able to state, however, that the wound is granulating slowly but well and without any sort of drawback. Gauze plugs are still being used for the dressings which, we are glad to add, are now quite painless. The KING sleeps excellently, no narcotics are, or have at any time been, employed. His general health is most satisfactory, he looks well and is in good spirits, but it must be borne in mind by his loyal subjects that, well as every thing is progressing, their beloved Sovereign is, as is only natural after having undergone such a severe operation, still an invalid and is at present restricted to the recumbent position. He is taking a diet of the very simplest description but is able to enjoy it. Sir THOMAS BARLOW has ceased to reside in Buckingham Palace but attends there every morning in consultation with his colleagues, Sir FREDERICK TREVES and Sir FRANCIS LAKING, who are both still in residence at the Palace. In view of certain detailed statements which continue to be made in a section of the press—statements which we are rejoiced to be able to stigmatise as lies—it is our duty, and a most pleasant duty it is, to say in the clearest possible terms that there is not, and that there never has been, the faintest shadow or ghost of suspicion of any malignant disease. The KING is free from cancer We trust that this definite pronouncement on our part will put a final stop to such cruel rumours. What their object may be we cannot conceive, but we may ask, How would they who spread them like such false tittle-tattle to be given to the world concerning their own dear ones? Have they no sympathy with, or consideration for, the gracious and sweet lady who, like the rest of the Royal family, has been passing through a period of such great trouble and anxiety?

The Summer Season

WITH each summer come a few weeks of genuine discomfort, followed in some instances by acute suffering, due to the excessive heat. This is an inconvenience which is more especially felt in large towns, and as the towns grow in size the more pressing does this grievance become. The central streets do not widen as the population increases and therefore become more and more crowded This does not so much matter in the cooler days of the year, but the very hot weather makes us long for more elbow-room Nor is it easy to escape, for, in London at least, the top of every omnibus is crowded, the inside is insupportable, [illegible] Metropolitan railway [illegible] where the unfortunate travellers are [illegible] by sulphurous fumes. Yet it is [illegible] much of the suffering [illegible] endured could be [illegible] by the adoption of a few practical measures [illegible] There is [illegible] prospect that the [illegible] electricity instead of steam [illegible] render railway transit more [illegible] and the [illegible] daily benefit of [illegible] persons. there is no reason [illegible] a manner as to admit of thorough ventilation [illegible] ducing a dangerous or at [illegible] draught. In any case, there are [illegible] tramcars with only canvas curtains [illegible] windward or to keep [illegible] the fear of reducing dividends by increasing the expenses this healthy and pleasant means of [illegible] would be more widely employed On the continent, the warm season lasts longer than in England, these summer tramcars are more extensively used

Apart from public services, each individual may, [illegible] exercise of a little thought and discretion, do [illegible] to lessen the inconvenience due to exceptional heat [illegible] difficulty is to persuade persons to alter their habits fo[illegible] season which in this country is of but short duration [illegible] the very fact that great heat is quite exceptional [illegible] therefore we are not accustomed to it, makes it all [illegible] more necessary to take proper measures. The healthy [illegible] strong may be only inconvenienced, but the feeble [illegible] aged may be seriously injured Obviously the first [illegible] caution is so to plan our appointments and business [illegible] to allow plenty of time to walk slowly from place [illegible] place. People who live in hot climates do not race, as we are in the habit of doing in England Also [illegible] hotter the climate the more general is the abstinence from alcoholic drinks. The thoughtless [illegible] however, rushes about with just as much energy [illegible] rapidity during the very hot weather as during the temperate periods of the year As a [illegible] soon overwhelmed with thirst and [illegible] mineral waters with a dash of alcohol [illegible] expensive he will take a glass of [illegible] condition and then at once hurry back [illegible] only increases the perspiration from [illegible] suffering In time, especially if the drinks are [illegible] reaction, headache, and general lassitude ensue. Such [illegible] *régime* is as inefficacious as it is injurious First of [illegible] we should strive to keep cool by moving slowly, then [illegible] must endure thirst and abstain from drink while [illegible] active. It is only when we have reached a [illegible] cool place and can sit and rest for awhile that we venture to quench our thirst. But then we come to face with this great grievance [illegible] suitable summer drinks in [illegible] a still greater lack of cool places [illegible] people can rest while taking [illegible] seething heat and foul atmosphere of our popular [illegible] houses constitute a standing disgrace and no [illegible] people would put up with such shamefully [illegible] accommodation In the centre of Paris, where [illegible] is as valuable as in London, the workman's [illegible] on a chair and a table placed in the shade and in the open air before he will consume a drink in the cheapest of *cabarets*. For the wealthier classes there are luxurious cafés well shaded from the sun, the windows removed, and the ground kept cool by constant watering Here, rest and a fresher atmosphere can be enjoyed together with a great variety of pleasant iced drinks that contain little or no alcohol. Why are we in England so much behind other nations in this respect? In Germany the town workman has in summer time numerous beer-gardens where there are shade and fresh air In due measure with the comforts and luxuries provided do we find a decrease in the prevalence of drunkenness. Drunkards abound in our public-houses, they are almost never seen in a French café, even though absinthe be served at every other table. All that has been said in favour of temperance and against strong alcoholic drinks is doubly appropriate during the very hot weather Then more than ever is a really good temperance drink urgently needed It does not say much for the practical sense of the temperance party in this country that they have never yet been able to invent such a drink. Light lager beer is, we believe, yearly more and more appreciated in England. This is truly a temperate drink well suited for hot weather As we have already shown by careful analyses beer of the Munich type contains as much nutriment with only half the alcohol that is to be found in typical high class English beers[1] Then it must be kept cool—namely at about 45° F which is better than being iced. There is also a larger demand for ' lemon squash or simple lemon juice with plain water and sugar and this is a good symptom, for these are the sort of drinks that will do no harm during the hot weather Tea is likewise taking the place of strong drinks and the hotter it is the more refreshing the after effect—a fact which is at last being recognised.

Altogether a great mass of the people are becoming wiser but there is yet plenty of room for improvement. While in our streets we lack suitable cafés terraces in the open air beer and tea gardens, our homes are not provided with the proper means to keep ourselves cool We want shutters that we can close to keep out the sun while we pen the windows to let in the air Verandahs are rare uxuries and awnings until quite lately have only been seen clubs or the houses of the rich. The walls of our smaller ouses are often so thin that we are exposed to the extremes heat and cold though here, again, legislation to defeat e jerry builder is improving our prospects. The Londoner -comparing in our mind our capital with the capitals of her nations—suffers more from the heat than do the habitants of those continental towns where, the houses eing larger, the walls are thicker and the indoor temperare is regular The Englishman rejoices in the independnce of having a house to himself but he has to pay a price r the privilege. Then in many continental towns it is stomary to close all offices and to stop all business om noon till two o clock so that there is no need to urry over the midday meal and some rest in a cool aded place can be enjoyed. Of course, such a rest would t be practicable in the City of London, where the work the world is done, but in the suburbs and in less proundly busy centres at least the younger and weaker members of families who remain at home might be allowed a siesta in the hottest part of the day It would be better for them to play to study, or to work in the cool of the evening When we have exceptionally hot weather we can with advantage imitate the customs of those peoples to whom such weather is a more usual experience than it is to ourselves.

The Fees of Medical Witnesses in Criminal Cases

WE recently discussed[1] in a leading article some of the conditions that arise when medical practitioners are called upon to give evidence in civil actions and in an answer to a correspondent in a subsequent issue[2] we further explained our views upon this branch of the question of the remuneration of medical witnesses. The hardships that press upon medical men in connexion with giving evidence are not, however confined to civil proceedings, but are even more oppressive in criminal trials. Our contention is not that medical men should be exempt from giving evidence or that they should give such evidence upon advantageous and profitable terms, but that the peculiar circumstances which make them liable to be called as witnesses more often than any other class of person not directly connected with the administration of justice should be recognised, and that where their evidence is necessary everything reasonable should be done to render their pecuniary loss and their disturbance in the practice of their profession as small as possible.

Recent cases have called attention to the unenviable position occupied by medical men in respect of criminal as distinct from civil trials and two of these may be brought to our readers notice. In one of them at Leeds, a medical man had attended a patient at the infirmary for injuries stated to have been inflicted by persons who had assaulted and robbed him. The medical man was not present when his name was called at the hearing before the deputy stipendiary magistrate, and two adjournments were made before he came. He afterwards explained that this was due on the first day to his not having been informed that he would be wanted and on the second day to a misapprehension as to the time, and he denied any desire to treat the magistrate with disrespect. His explanation seems to have been accepted, but apparently before he had had the opportunity of giving it he had been informed by the magistrate in open court that had he not appeared a warrant would have been issued to bring him in which case had he refused to give evidence he would have been sent to gaol. We need not discuss the good taste of fulminations of this kind they do not, however tend to render the situation of the medical man less irksome and objectionable. In the second of the recent case to which we have referred, on the trial of an indictment at the Suffolk assizes against a prisoner for indecent assault upon a little girl, the police informed the judge that each of the three medical men in the town where the child lived had refused to examine her on the ground that the fees allowed in connexion with criminal proceedings were inadequate. The judge appears to have adopted a somewhat different tone to that employed by the magistrate at Leeds and to have intimated his intention of calling the attention of the Home Secretary to the matter These two cases illustrate the two main causes which lead to medical men becoming witnesses in criminal courts by virtue of their profession The first case belongs to that class which practically compels the medical man to be a witness whether he will or not He is summoned to attend a person who is injured, perhaps seriously, but who is alive, and he can hardly stay to inquire whether rendering surgical aid, which may be necessary to save life, will make the surgeon a necessary witness at a criminal trial. Cases of the second class are those in which the medical man is invited to give evidence which only a medical man can give, but with regard to which there is nothing to indicate a particular practitioner as the witness to be summoned. Such cases not infrequently occur in country districts, where sexual offences constitute a large proportion of the charges which are tried at assizes and quarter sessions It may be in such a case that a man is charged with unlawful carnal knowledge of a young girl There is absolutely nothing about her that calls for medical aid and the medical man is only expected to examine her genital organs and to say in the witness box whether in his opinion the conditions he has observed are consistent or inconsistent with the charge made It can scarcely be a matter of surprise that medical men should hesitate to make an examination at such a juncture knowing that the pecuniary reward will be trifling and that the inconvenience and waste of time incurred will be considerable

---

[1] THE LANCET Feb. 16th 1895, p. 429

[1] THE LANCET J 18th 1902, p. 170

[2] THE LANCET June 28th 1902, p. 1,5

It must not be thought that in either of the two classes of case to which we have called attention we would wish to see the trial conducted without medical evidence. We make no such suggestion, but our contention is that a man who has to earn his living in a certain profession should be reasonably compensated if he is wanted as a witness and that his time should not be wasted unnecessarily With regard to the present scale of compensation, the fee of a medical man for each day that he shall necessarily attend a court to give medical evidence does not in any case exceed a guinea, while there are allowances—such as *3d* per mile if he lives at a distance and *2s* as a contribution to the price of his night's lodging, if required—which are equally inadequate. Without discussing the prescribed fees and allowances in detail we would point out that they were fixed in the middle of the last century by Sir GEORGE GREY (the grandfather of the present Sir EDWARD GREY), Home Secretary during one of Lord PALMERSTON'S administrations This alone should suggest that at the present date revision might be an act of justice. More important, however, than the actual amount of fees paid, is the question of inconvenience and disturbance. It may be that if the daily reward of the medical man for giving evidence were doubled or trebled, care would be taken to economise the public funds by occupying as little of his time as possible. Loss of money is not the only loss that he has to put up with He has to leave his practice for an uncertain time, to waste precious hours doing nothing, and to feel frequently that the waste might be avoided Many hours of waiting and inactivity there must be where a number of witnesses are summoned, for instance, to a country assize of a week's duration, but will any medical man who has endured such an experience assert that some part of the worry which was occasioned to him might not have been avoided by the exercise of care and organisation combined with consideration? Consideration is due to those who may have important cases of illness under their charge at home demanding their personal attention, and consideration is due to their patients Medical men under the present system, when bound over to give evidence on a certain date, often do not know whether the trial in which they are witnesses will be concluded on that day or whether they may be kept for four or five days waiting for it to come on, and in consequence can make no proper arrangements for the care of their patients. They are, moreover, not infrequently retained in attendance without any information or permission to retire temporarily being vouchsafed to them, although such information or permission might safely be given To these the inadequacy of the fee under the present scale may seem almost insulting but under whatever scale it was paid it would not compensate them for absence from practice coupled with the idleness and uncertainty needlessly imposed upon them

The Accident to Mr Chamberlain.

IN the early days of railways it used to be said that accidents would continue to occur until a director had been killed in one. Now that a Cabinet Minister has been severely injured in a cab accident and treated at a hospital we may hope to see two reforms brought about, firstly, a more generous appreciation of the hospitals by the well to do classes, and secondly, the abolition of the dangerou moveable window of the hansom With regard to the firs point we would recall to our readers the followin passage from the Hospital Sunday Fund Supplement whic appeared in THE LANCET of June 16th, 1900 In speakin of the reasons why the well to do should give to the hospital we said —

> "Let the giver, if he wants self-interest as well as charit for a motive, remember that the help he confers upon th hospitals may some day come back a hundred fold upon himself He may not belong to the class with which accident are frequent in their daily work, but some day a misha may lay him low so that the saving of his life may depen on the promptitude of succour The doors of the neares hospital will stand open for him as widely as they do for th labourer or for the poorest beggar in the streets His lif may depend upon the application of some new discovery c science, and let him remember that it is in the hospitals tha such discoveries are brought to perfection "

Now, we do not suggest that Mr CHAMBERLAIN'S lif would have been endangered if he had been drive straight home, there to be attended by his medica man, instead of to Charing Cross Hospital, where h was conveyed on the advice of a policeman Althoug wounds of the face or scalp bleed with astonishin freedom, yet owing to there being a hard bony surfac against which to exert pressure the hæmorrhage ca always be arrested, at least temporarily, by pressur on the wound. But the fact remains that he di not go home but was taken by a policeman to general hospital, exactly the same procedure bein followed as would have been had the victim been th cabman or a street waif who had been knocked down by the cab. Arrived at the hospital he was attended to by the house surgeon on duty and the resident medical officer and was detained for the night. A similar accident might happen to anyone on any day and Mr CHAMBERLAIN'S misfortune ought to impress upon the ordinary well to-do citizen that he may one day need a hospital and that therefore he ought to help to support those institutions with gladness and with such liberality as he can afford. We do not suggest that the selfish motive is the really important one but while charity should impel all to support the hospitals it tells in favour of those hospitals that they afford relief to rich and poor alike.

Secondly, is it impossible that a hansom should be rendered a less dangerous vehicle than it is? As at present constituted the sliding window is a really perilous affair If let down it makes the interior unbearably stuffy while if the horse should chance to fall when the window is down the head of the fare is nearly certain to go through the glass and nasty cuts are inflicted. If, on the other hand as in Mr CHAMBERLAIN'S case the horse falls when the window is up the strap breaks or comes unfastened, with the result that the window falls somewhat after the fashion of the axe of a guillotine. Hansoms have been made which are entered at the back, but though this plan does away with the falling window it does not protect the head of the fare if the horse should go down. Is it impossible to manufacture a window which would go up and down like a roller blind? This would obviate any danger of the window falling and although the fare's head might still be projected through it, yet, as it would not be made of glass, but little harm would be done. The material to be used offers difficulty If transparency is required something of the nature of celluloid would seem to be indicated though transparent celluloid is dangerous on account of its high degree of inflammability But is transparency a necessity? The present window of a hansom is almost never let down except on account of rain—rain, moreover which drives in an exactly opposite direction to that in which the hansom is going so that vision is much impeded. It would seem therefore, that the uses of the window of the hansom are very limited certainly they are not commensurate with the risk which the public is invited to take. Cannot mechanical ingenuity contrive a substitute?

"Ne quid nimis"

DEATH OF DR JOHN CURNOW

THE death of Dr John Curnow which occurred suddenly on Saturday last, July 5th has come as a shock to a large circle of friends, which practically includes everyone educated at King's College Hospital for over 30 years. To ourselves and to all the senior members of our staff the news of his death brought a deep sense of personal loss for Dr Curnow had been connected with the editorial staff of THE LANCET for more than a quarter of a century We shall publish in an early issue an extended obituary notice of our dead friend who's brilliant record as a young man sound scientific attainments, love of right and scorn of humbug, and unfailing good temper and kindness of heart entitle him to more than mere passing notice. A memorial service was held on July 9th at King's College Chapel and the funeral took place on the same day at Highgate. Besides the two sisters and brother in law of the deceased there were present various friends of the family From King's College Hospital there came Dr N Tirard Dr N Dalton Mr W Watson Cheyne Mr P T Beale, many of the resident medical officers and of Dr Curnow's clinical clerks the sisters of his wards, some nurses and Captain H. S. Tunnard, the secretary Dr H. P Cholmeley represented THE LANCET and Dr Herbert Smalley of the Prison Commission attended as an old King's College Hospital man and a personal friend of long standing

A CASE FOR PUBLICITY

WE have already discussed the affairs of the Royal Orthopædic Hospital under this heading and may assume that the details of the unfortunate plight in which the institution is placed are familiar to most of our readers Roughly speaking the situation is this. The hospital owns a freehold of great value, the committee of management proposes to sell that freehold and certain governors and members of the medical staff think that to do so is suicidal Undoubtedly a large sum of money would be received from the sale, but equally undoubtedly the freehold is one that will increase in value so that, unless urgency can be pleaded, on the face of it the sale should not be made. But if on behalf of the patients urgency is required no pecuniary considerations must interfere with immediate sale. A hospital should be run for its patients. We have recently had an opportunity of inspecting the buildings of the Royal Orthopædic Hospital when every possible courtesy was offered to our representatives and every facility was given to them for framing an opinion upon the whole question. The conclusions which were come to by our representatives, one of whom we may say was an architect, and both of whom were perfectly familiar with the requirements of a modern hospital were as follows. The Oxford-street end of the property where of course, the enormously valuable frontage is situated must be condemned *in toto* as a fabric. At the present time this building is given up to an out patient department of unsatisfactory aspect and imperfect equipment having above it certain leaky little rooms for nurses. The Hanover square end of the property which is now being used as a hospital for some 40 beds, a large proportion of the patients being children, is in better case. It is not a modern building and is without many of the conveniences of a new hospital but the wards are airy light, and clean, and the fabric has recently been put into good sanitary repair That this building will in course of time have to be replaced by a properly equipped structure, should the hospital remain upon its present site is undoubted but the state in which it now is does not allow urgency to be pleaded as a reason for moving In the circumstances it seems to us that the policy of the hospital should be to build upon the Oxford street end of the property when it would certainly obtain a very large rent for the ground floors—perhaps as much as £1000 per annum Above the shop could be placed proper accommodation for the matron nurses and servants. In this way the matron's room at present in the Hanover square building would be free for occupation by a resident house surgeon. The Hanover-square end of the building—that is to say the hospital proper—could be made to do for a further period until the enhanced value of the whole property enables either a better sale to be made or a new hospital to be constructed upon the present site Absolutely no proof of any urgency is forthcoming 40 beds out of the 60 which the building will possibly hold are occupied, and the income of the hospital does not suffice to keep more than that number filled. These are our views and we have heard nothing from those responsible for the policy of an immediate sale that leads us to alter them. We do not say that the committee of management has no reason for what it proposes, but we do say that it is singularly reticent, considering that it is dealing with a public charity. The whole case is one for publicity. Why must the site be sold at all? Why must it be sold at once? And if it must be sold at once, why is not its proper price ascertained in the usual way by putting the property up at Tokenhouse yard? It is possible that an answer to some of these questions may now be forthcoming, for on Wednesday afternoon last an inquiry into the matter was held at the hospital by the Charity Commissioners. The inquiry was conducted by Mr. G. S. D. Murray, assistant commissioner, when the strong case for those opposed to immediate sale was put forward. The Charity Commissioners are not likely to sanction any sale upon grounds that will not bear public investigation and free discussion.

LACHNANTHES

WE publish an interesting communication this week on the chemical and therapeutic properties of lachnanthes, that much discussed drug in regard to its alleged value in the treatment of tuberculosis. By following well-recognised chemical methods Mr. J. A. Gardner, M.A., F.I.C., has been able already to separate from the extract chemical entities which no doubt under further study will resolve themselves into substances of definite chemical composition. Thus, to quote one instance, a syrup was obtained which on standing for some weeks deposited crystals. The nature of these and other bodies will be elucidated, it is hoped, as a sufficient supply of the material is gained. Lachnanthes evidently consists largely of resinoids and further, perhaps, contains bodies of the nature of alkaloids. At any rate, an aqueous extract of the material is very distinctly toxic and far from any inhibitory action being shown upon the progress of tuberculosis the injection of the extract would seem to hasten it. These preliminary results are of sufficient interest to warrant extended inquiry and the indications of further experiments will be awaited with interest. The biological part of the inquiry was undertaken by Dr. Harold R. D. Spitta and Dr. Arthur Latham.

SUTURE OF WOUNDS OF THE HEART

A DIRECT result of the antiseptic method has been the bringing of every region of the body within the field of the operator. In consequence of obvious peculiar difficulties the heart has been the last territory encroached upon by modern surgery. Indeed, the number of operations performed on it are still very few. At the recent annual meeting of the American Medical Association Dr. Harry M. Sherman devoted his "Oration on Surgery" to "Suture of Heart Wounds" and presented a useful summary of our present knowledge of the subject. In 1896 the heart was sutured three times for wounds, in 1897 twice, in 1898 four times, in 1899 11 times, in 1900 three times, and in 1901 nine times. This year two operations have already been reported. All the wounds were punctured or incised except two bullet wounds. The ventricles were injured 32 times, the auricles twice—the right being opened in one case and the left in the other. In most of the cases in which details are given the pleura was wounded and usually there was hæmothorax. The method of operation varied: either a flap of all the tissues of the thoracic wall was turned up or a resection of two or more ribs was performed. Three operators used catgut for suturing the heart. In the other instances in which the material is specified silk was used. In most cases the sutures were interrupted, in a few they were continuous. Inclusion of the endocardium was avoided. The thoracic flaps were, of course, replaced; in seven cases drainage of the pleura and pericardium was performed, in four of the pleura alone. Of the 34 patients five died on the table from hæmorrhage or shock and 10 soon afterwards. These deaths were probably inevitable under any conditions. Of the remaining 19, 13 recovered and six died from sepsis. In not one instance was death due to secondary hæmorrhage. Thus the suture of the heart in all the 19 cases was a perfectly successful operation for the arrest of hæmorrhage. The symptoms of wound of the heart are an external wound in the pericardium, the general signs of hæmorrhage, disturbance of cardiac function, and signs of filling of the pericardium and pleura. The left pleura extends so close to the sternum that practically a wound of the heart implies penetration of the pleura. Also in exposing the heart for suture opening of the pleural cavity is unavoidable. In the *Münchener Medicinische Wochenschrift* of Jan. 16th, 1900, Dr. Rotter has carefully described a method of exposing the heart so completely that even the posterior surface can be reached.[1] In it a flap is formed containing the inner ends of the fourth and fifth ribs which are divided and luxated from their sternal attachments. The flap of thoracic wall is turned inwards like a door on its hinges. The subject is of wide practical importance, for suture of the heart, like herniotomy and tracheotomy, is an operation of emergency which any medical man should be prepared to undertake. If hæmorrhage into the pericardium is not arrested when the limit of pericardial distensibility is reached the heart is unable to dilate and its movements are mechanically stopped.

DISTRIBUTION OF MEDICAL PRACTITIONERS IN THE UNITED KINGDOM

A CORRESPONDENT has been making investigations into the distribution of medical practitioners or professors in the following places in the United Kingdom where the greatest number of them are congregated. He finds that the average number of medical persons in those places per 10,000 of the population works out as follows:—Clifton, 36 80; Bournemouth, 24 38; Harrogate, 21 11; Cambridge, 21 09; Weston-super-Mare, 20 47; Bath, 20 07; Brighton, 19 51; Edinburgh, 19 14; Southport and Birkdale, 17 66; Tunbridge Wells, 17 07; Torquay, 16 65; Eastbourne, 15 46; Bedford, 15 36; Oxford, 14 16; Dublin, 13 83; Scarborough, 13 36; Hastings and St. Leonards, 13 05; Glasgow, 12 80; Cheltenham, 12 33; Cork, 10 92; Blackpool, 10 56; Aberdeen, 10 45; Waterford, 9 72; York, 8 86; Plymouth, 8 55; Wakefield, 8 42; Limerick, 8 13; Newcastle-on-Tyne, 7 91; Cardiff, 7 78; Lancaster, 7 68; Southampton, 7 53; Londonderry, 7 49; Birmingham, 7 29; Birkenhead, 7 21; Croydon, 7 17; Belfast, 6 59; Stockport, 6 51; Manchester and Salford, 6 41; Nottingham, 6 38; Liverpool, 6 33; Portsmouth, 6 02; Preston, 6 01; Wolverhampton, 5 94; Leeds, 5 75; Derby, 5 57; Bootle, 5 46; Huddersfield, 5 36; Blackburn, 5 33; Northampton, 5 28; Great Yarmouth, 5 26; Bradford, 5 19; Sunderland, 5 11; Halifax, 5 05; Leicester, 5 05; Oldham, 5 02; Norwich, 5 01; Sheffield, 5 01; Paisley, 5 00; Bristol, 4 89; Burnley, 4 84; Hull, 4 65; Rochdale, 4 45; Dundee, 4 40; Middlesbro' on Tees, 4 38; South Shields, 4 31; Bolto 4 16; Walsall, 3 93; Leith, 3 67; Gateshead, 3 63; and St. Helens, 3 31. In London there are about 12 medical perso per 10,000 of the population. The 24 cities in the Unite Kingdom which contain the largest number of medica practitioners or professors are the following, placed i numerical order—viz. London, Glasgow Edinburgh Manchester (including Salford) Liverpool, Dublin, Birmingham Leeds Brighton Belfast Sheffield, Newcastle-on Tyne Aberdeen, Bristol, Bradford, Bournemouth, Nottingham Cardiff, Portsmouth Hull, Southport (including Birkdale) Clifton Leicester and Bath The above figures are based upon information comprised in the Medical Directory 1902, which contains in the London list 6292 names, in the Glasgow list 732 names, and in the Bath list 100 names. Some of the medical persons however have retired and a few are travelling

---

[1] THE LANCET, Feb. 16th, 1901, p. 491.

THE PREVALENCE OF SMALL-POX

THE following figures show the number of patients admitted to the various hospitals of the Metropolitan Asylums Board for the dates mentioned on Saturday, July 5th there were six fresh cases on Sunday, the 6th there were four fresh cases on Monday the 7th there were seven fresh cases, on Tuesday the 8th there were 6 fresh cases, and on Wednesday the 9th, there were 5 fresh cases.

ACROPARÆSTHESIA: AN ANALYSIS OF 100 CASES

AN important study of the somewhat rare nervous disorder known as acroparæsthesia is contributed by Professor Joseph Collins of New York to the *Medical Record* of May 31st last Acroparæsthesia is characterised by abnormal sensations in the extremities principally those of pricking tingling 'pins and needles, and numbness. The present contribution was based on the study of 100 cases observed during the past five years at the clinic of the New York Post-graduate Medical School Symptoms allied to acroparæsthesia are often associated with such bodily conditions as chronic rheumatism gout, and other arthritic disturbances, peripheral neuritis, diabetes, and pulmonary phthisis but such cases were excluded from the present research which concerned itself only with cases where the acroparæsthesia itself was the only manifestation of disease or where other manifestations could not be found. As a typical case among the many cited by the writer the following may be given. A woman, aged 68 years suffered from symptoms of numbness and tingling of the hands and arms soon after retiring to bed. When the pain or discomfort reached its height she would awake and rub her fingers and hands till relief was obtained and then go to sleep again. This occurred five or six times every night and prevented her sleeping soundly It was found that she had been overworking herself to the point of fatigue for some time preceding the illness and was also suffering from constipation. The symptoms soon ceased and did not recur Among the 100 cases the average age when the symptoms appeared was 39 years most of the patients being between the ages of 30 and 50 years. There were 69 females to 31 males and most of the latter were Jews of the lower class. Among diseases which preceded the ailment were rheumatism, influenza, typhoid fever pneumonia, or ill health from alcoholic intemperance but in not one case was syphilis ascertained to have been present. As regards distribution of the symptoms in 52 per cent. of the cases they were in the arms and hands in 10 per cent. in the feet and legs and in 30 per cent. in both the upper and lower extremities. In the remaining few cases they were present in other parts of the body and only in a single case in the face Associated gastric disorders were present in many cases—viz. constipation in 32 per cent. anorexia and coated tongue in 15 per cent. and gastro-intestinal fermentation in 10 per cent of the cases. 14 patients complained of headache and 11 had marked neurasthenic symptoms. The peripheral circulation was slow and feeble, the pulse was small and the hands and feet were clammy in 20 per cent., but in no case was sclerodactylia or Raynaud's disease present in the whole series. The average duration of the symptoms of acroparæsthesia was 14 months. The occupations in which it was most prevalent were those involving overwork with the hands, as in the case of tailors washerwomen and laundry workers but gastric disorder or constipation predisposed to it. The treatment consisted of rest, 'tonic baths" (cold water splashing of the body and limbs at from 65° to 75° F followed by vigorous rubbing of the back and abdomen) galvanisation of the cervical and brachial plexuses a diet to correct constipation and the administration of arsenic and strychnine as nerve tonics. The pathology of the disease remains, adds Professor Collins, as yet obscure

PRESERVED SHRIMPS AGAIN

ON more than one occasion we have referred in our columns to the increasing sale of shrimps imported from Holland preserved with excessive quantities of borax. It appears that an enormous amount of Dutch shrimps are imported for distribution as fresh English shrimps. Apart from the deception which is thus practised the shrimps contain very large amounts of borax or boric acid, equal to about 41 grains per pound of the acid According to the recommendations of the Departmental Committee on Food Preservatives borax is permitted to be used in cream, butter, and margarine in certain amounts which are not to be exceeded. The recommendations, however do not relate to other articles of food, such as shrimps, and, therefore, we may take it that these could be treated with an unlimited amount of borax. Imported shrimps so preserved are obviously however not of the nature and substance demanded, as of course, they are not English shrimps. Such was the view taken by the bench in the case tried recently at Ormskirk. During the hearing of the case it was stated that an old industry was threatened with ruin by the introduction of foreign shrimps. It would be interesting to know what view would be taken in the case of other fish, such as salmon, which let us assume, was sold as fine Scotch salmon but which proved to be an imported fish preserved in the same way as are Dutch shrimps.

ON THE USE OF TRIANGULAR DIAGRAMS FOR THE REPRESENTATION AND COMPARISON OF DIFFERENT TYPES OF SKULL.

Professor W M. Flinders Petrie, the Egyptologist, has devised an ingenious method of representing the principal cranial indices by means of a system of diagrams which clearly exhibit their characteristic features even though they may be drawn so small that a threepenny piece will cover them. The principle is fully explained in the June number of *Man*, a journal published under the direction of the Anthropological Institute of Great Britain and Ireland. A vertical line is drawn on paper and from its lower extremity two other lines are drawn making with it angles of 120° The three lines therefore meet in a point, like radii of a circle, and are equally inclined to one another Any scale of equal parts being taken and the numbers corresponding to the three principal measurements of the skull being found upon it, the vertical line is made equal to the number of divisions representing the height of the skull the line sloping downwards to the left is made equal to those representing the length of the skull and the line sloping downwards to the right is made equal to those representing the breadth of the skull Then by joining the outer ends of these three lines a triangle is formed the inclinations of the three sides of which show the ratios (1) of the length to the breadth, (2) of the length to the height, and (3) of the breadth to the height. The indices of different skulls obviously may be compared by observing the slope of the corresponding sides of the respective triangles—e.g , with a brachycephalic skull the base line will slope downwards from left to right, while with a dolichocephalic skull the base line will slope downwards from right to left Moreover, in these triangles the whole area varies with the capacity of the skull, and the area of each of the three triangles within the large one varies with the area of the three cross sections of the skull, vertical fore and aft section being shown by the left-hand inner triangle, vertical cross section by the right hand inner triangle, and horizontal section by the lowest inner triangle In order that two or more triangles may be comparable with one another it is obvious that the same scale of equal parts must be used in setting out the lengths of the three central radiating lines Ethnological classifications of a more elaborate kind can be obtained in a graphic and compact form by superimposing these cranial triangles upon paper ruled in squares which in the horizontal direction show the transition from the orthognathous to the prognathous type and in the vertical direction the transition from the wide-nose type to the narrow nose type.

THE HENRIETTE RAPHAEL NURSES' HOME

ON July 7th the Prince and Princess of Wales visited Guy's Hospital and opened the Henriette Raphael Nurses' Home, which was founded by the late Mr H. L Raphael in memory of his wife. The erection of the home has cost about £68,000, and towards this sum the late Mr Raphael gave £20,000 The building contains, besides living rooms, 213 bedrooms, a sick ward, and a swimming bath In reply to an address of welcome by Mr Bonsor, the treasurer of Guy's Hospital, the Prince of Wales said - -

> Mr Treasurer, my Lords, Ladies, and Gentlemen —before I allude to the object for which we are met together to-day I am sure that all who are here will join with me in expressing our feeling of unbounded thankfulness to God for the merciful recovery of my dear father the King And speaking before the authorities of one of our leading hospitals I should like to say that we who have watched at the sick bed of the King fully realise how much, humanly speaking is due to the eminent surgical and medical skill as well as to the patient and highly-trained nursing which it has been His Majesty s good fortune to enjoy So it seems almost fitting that one of the first public ceremonies that the Princess and I should take part in since the King s serious illness should be to open this beautiful home for nurses within the precincts of this great hospital which we have just had the pleasure of inspecting It is only in comparatively recent times that the rôle of the nurse in the sick room has been fully recognised But are there not many here who like myself will throughout our lives remember with the deepest gratitude the soothing comfort indeed I may say the blessing of efficient nursing? Recognising therefore the high and indispensable position which nurses occupy, the least that can be done for them is to provide the comforts of a home where they can enjoy rest and relaxation after their hours of arduous and self sacrificing work It was one man who holding this view gave practical reality to it by the munificent gift already referred to by the treasurer for the purpose of establishing this home which we to-day inaugurate and I am glad as your President to congratulate Mr Raphael who I am happy to think is one of our governors, upon the consummation of the work of which his father was the founder and which for all time will bear the name of his mother I now have much pleasure in declaring the Henriette Raphael Nurses Home open

THE REPORT OF THE JOINT SELECT COMMITTEE OF THE TWO HOUSES OF PARLIAMENT ON THE LONDON WATER BILL.

THE ' Report and Special Report from the Joint Select Committee of the House of Lords and the House of Commons on the London Water Bill with the proceedings of the Committee" have been recently published.[1] The gist of the proceedings and the practical outcome of the report have already been given in THE LANCET and the nature of the special report has been correctly foreshadowed. The information given which is new to us is the way in which the members of the committee voted at the various divisions The first important division was that which took place on April 30th on the constitution of the proposed Water Board Lord Balfour of Burleigh proposed that ' the committee accept in its general lines the composition of the board as set out in the third schedule," and to this Lord Llandaff proposed an amendment to leave out all the words after "committee" and to insert instead the words "delete the representation of the metropolitan boroughs from that schedule " Those who supported the amendment were the Earl of Crewe, Lord de Mauley, Sir William Houldsworth, Sir James Kitson, and Mr M'Crae Those in favour of the Government proposal were Lord Balfour of Burleigh, Lord Ludlow, and Sir William Arrol It will be remembered that the Government made a strong appeal to the committee to reconsider its decision, and the President of the Local Government Board himself was present. On May 6th the committee decided to receive evidence tendered by the metropolitan boroughs with reference to the proposed Water Board. This course practically reopened a question which had been already decided, and those in favour of the proceeding were Lord Balfour of Burleigh, Lord Ludlow, and Sir William Arrol (who were from the first in favour of the Government measure), Sir Edgar Vincent (who was not present in the earlier division), and Lord de Mauley, Sir William Houldsworth, and Sir James Kitson, who practically changed sides The final decision as to the constitution of the Water Board was made on June 11th and the result really depended on the way in which the question was put. Lord Balfour, Lord Ludlow, Sir William Arrol, Sir William Houldsworth, and Sir Edgar Vincent were in favour of the Government proposal, the Earl of Crewe, Viscount Llandaff, Lord de Mauley, Sir James Kitson, and Mr M'Crae were opposed to it. The special report drawn up by Lord Balfour of Burleigh in regard to the way in which the decision was arrived at is as follows —

> On the question of passing the schedule as a whole the chairman was requested to put the question, That the schedule stand part of the Bill," but he gave it as his decision that he should not so put the question, but that if such motion were made he should put the question in the form ' That the schedule be disagreed to" The question having been thus put and the numbers being equal the chairman (having in accordance with precedent no casting vote) ruled that the said schedule must stand part of the Bill on the principle that no amendment should be made to the Bill as referred to the Committee by the House after second reading unless there should be a majority in favour of such amendment

THE WATER-SUPPLY OF LIVERPOOL

THE annual report of the engineer of the City of Liverpool Waterworks[1] has recently been published A full account of the sources of supply has been given in THE LANCET and on that point nothing need be added The most interesting part of the present report is that which relates the difficulties which have occurred owing to the obstruction to the flow of unfiltered water through the pipe which conveys it from Lake Vyrnwy to Oswestry An elaborate series of experiments has been made and the information which has been obtained from them will be of the greatest service to all those who have the responsibility of conducting upland water for long distances for the supply of cities It may be of use to state in the briefest possible manner the difficulties which have presented themselves, the nature of the investigation which was adopted to discover their cause, and the new facts which have been established as a result of the investigation. The trouble arose from the fact that the pipe which conducted the unfiltered water delivered a quantity considerably less in amount than it should have done—roughly speaking, about one seventh less Mr Deacon's pipe cleaning apparatus—a specially devised brush—was used with good results and the process of cleaning the pipe occupied about 10 days. The trouble recurred. Experiments were undertaken with a view to determine the exact nature of the obstructing matter and the best method of preventing its accumulation. Professor J Campbell Brown, D Sc., *found incrustations on the inner surface of the* pipes, that these were due mainly to corrosion that there were growths of organisms and that the flow of water was checked partly by the diminution in the lumen of the pipe and partly by the increased friction set up by the nodosities on its surface Accumulations of débris of mineral and organic substances were found. Professor Campbell Brown recommended that the pipes should be treated with pitch and that lime should be added to the lake water Filtration he recommended as perhaps a less important measure. The most interesting part in his report is to the effect that he has ascertained that a great deal of the colour of Vyrnwy water is due to an organic compound of iron, and not to peat, as is popularly supposed. Professor Rubert Boyce has made a very thorough examination of the matter which is deposited from the Vyrnwy water as seen in specimens taken from the lake at different depths from the settling reservoir at Oswestry and from the aqueduct which carries it from the lake to the reservoir The deposit has the appearance of coffee-grounds, is rich in iron, contains some manganese and a fungus of undetermined name, of thread like appearance, gelatinous nature, and oxide-of iron forming properties. Although the presence of the organism is advantageous in so far as it precipitates some of the iron contained in the water it is highly inconvenient that the deposit should occur in the pipes. The elimination of the organism is therefore desirable, and Professor Boyce believes that the best method of accomplishing this is by the process of filtration, and Mr Joseph Parry the engineer to the waterworks agrees with this view The chief practical point which the investigation has brought out is that in the case of upland waters there is strong evidence in favour of placing the filter beds as near as possible to the gathering grounds.

HORSE-DUNG IN LONDON STREETS

FEW of the sanitary problems of large towns more urgently require to be dealt with than the constant fouling of the streets by the droppings of the countless horses which daily thread the busiest thoroughfares and few at present receive less notice, for even the nimble youth with brush and pan, at one time a familiar object, is fast vanishing if not quite extinct, and the only attempt apparently now made to deal with the problem is to water spasmodically the surface of the roads by day and to sweep them by night. Apart from the disgust occasioned by the sight of roads thickly powdered with dried or drying manure and the offensive smell exhaled as evaporation proceeds particularly from the sodden surface of wood paved thoroughfares there is the discomfort caused as the result of the dried floating particles, stirred by the wind or the traffic in the streets irritating the nasal mucous membrane and conjunctivæ, while the pathogenic possibilities must not be forgotten. Intestinal bacteria certainly flourish in the large intestine of herbivora as well as of carnivora, and apart from these the dejecta, especially when moistened, may well form a culture-medium for other organisms It is at any rate possible that some of the cases of conjunctivitis or of catarrh of the throat and nose may if not actually caused at any rate be predisposed to by the persistent irritation set up It is no uncommon thing especially on a slightly windy day to see the dried material swept by the wind into a thick layer at one side of the road and pedestrians walking in a thin haze of irritating particles. It is of course, easier to point out a nuisance than to remedy it but surely it is imperative, in the interests of public comfort and not improbably of public health, that municipal authorities should endeavour to find some means of dealing with this matter possibly some light form of mechanical scavenger—motor propelled—might be contrived so as to pass sufficiently rapidly over the surface of the road as not to impede the general traffic.

WALL-PAPER AND VENTILATION

IN a recent number the *Builder* draws attention to the influence of wall papers on the ventilation of rooms. With doors and windows closed the atmospheric contents of an unpapered room undergo change at the rate of one-twenty fifth of the whole per hour for each degree of difference between the inside and the outside temperatures. Supposing the external air to be at 35° F and the internal air to be at 60°, a complete renewal would take place in an hour by means of transpiration alone. When rooms are papered however the rate of diffusion is much slower not exceeding one-eightieth of the whole per degree per hour Should the paper be varnished the rate falls still lower while cemented and painted walls are almost impermeable. As very little provision is designedly made for ventilation in ordinary dwelling houses and especially in those at low rentals the subject is one well worthy of consideration by architects and builders Thanks to the jerry builder with his green wood fittings the wholesome outside air can make its way into many a dwelling house that otherwise would be uninhabitable but ventilation through cracks and fissures is of course, objectionable as it gives rise to draughts The employment of reasonably porous building material should be advocated in all new constructions but when, for any reason impermeable material is used the provision of scientific ventilating media should be made a *sine qua non*

ASPHYXIA FROM PRESSURE ON THE CHEST

THOUGH asphyxia from pressure on the chest is a well recognised cause of death the symptoms have been seldom studied because the condition usually is rapidly fatal. We have already described one case in which the patient survived [1] In this a peculiar mottled dusky bluish appearance of the skin was produced which differed from cyanosis in that it did not disappear on pressure and persisted after the patient improved In the *Boston Medical and Surgical Journal* of May 15th another case is recorded by Dr H. H. A. Beach and Dr Farrar Cobb It is of special importance not only on account of its rarity but also because a piece of the affected skin was removed during life and examined A healthy muscular man, aged between 30 and 40 years, was caught in an elevator and held for fully three minutes His face turned black. his eyes protruded and he bled from the nose When set free he was unconscious for a few minutes. An hour later when he was admitted to hospital he was conscious but stupid and in a state of moderate shock. The skin of the face was dotted with countless closely set spots from black to reddish black or blue in colour Between them were minute areas of normal skin. In the neck in front there was a sharp line of demarcation behind the discolouration corresponded to the position of the trapezii muscles a fact which has not been noted in any other case There were signs of severe injury from the groins and buttocks to the middle of the thorax several contusions of the abdomen, a large fluctuating hæmatoma in the left loin and back, and fracture of the eighth and ninth ribs in the axillary line with subcutaneous emphysema in the neighbourhood. Pressure on the blue black skin had little effect in causing it to become pale. The patient was never very ill except on the third day when his temperature rose to 106° F and his breathing was difficult both lung were full of râles and the expectoration was somewhat bloody This condition, however passed away in 24 hours The hæmatoma in the back was aspirated six times, each time from one to two pints of bloody serum were withdrawn and each time the fluid reaccumulated with great rapidity The discolouration of the skin faded rapidly after the third day and the intermediate areas of normal skin became larger In contrast to this subconjunctival hæmorrhages, which were present, went through the usual changes observed in absorption of blood. A piece of discoloured skin was removed from the neck and examined microscopically The section showed nothing abnormal This bears out the view advanced by Dr Ollivier, who examined the bodies of 23 persons crushed to death by the rush of the mob in the Champs de Mars in 1837, that the discolouration is due to stasis of hyper-venous blood in dilated capillaries. All the cases examined post mortem have shown changes characteristic of venous engorgement—distended great veins and punctate hæmorrhages on the surfaces of the viscera. But why was the remarkable discolouration of the skin confined to the face and neck? In the case previously described in THE LANCET[2] it extended as low as the third rib No satisfactory answer to the question is apparent.

[1] THE LANCET, Jan. 25th 1902, p 245.

A MEDICAL RESEARCH INSTITUTE IN THE FAR EAST

WE have received from the office of the Resident-General at Selangor an intimation to the effect that the Government of the Federated Malay States has established in Kuala Lumpur, the capital of the Federated Malay States a research institute which is open to all workers irrespectively of nationality The medical department is fully equipped for special and general pathological work, for the scientific study of clinical medicine, and for experimental physiology and bacteriology It includes a modern mortuary with a refrigerator chamber, a department for both organic and inorganic chemistry, a well-equipped photographic department, facilities for biological research, and a good working library It is stated that to the members of scientific commissions who visit the Malay Peninsula and neighbouring islands the institute affords an excellent opportunity for working up and preparing collected material Students of tropical medicine will find there an ample field for work. Beri beri is prevalent and malaria exists in at least four distinct types The institute is at present under the direction of Mr Hamilton Wright, M.D McGill, to whom any communications in reference to the institute may be addressed

THE DESTRUCTOR NUISANCE AT TORQUAY

IN our issue of June 14th, page 1706, we adjured the municipal fathers of Torquay to endeavour to render their beautiful town worthy of its reputation as a health resort. The destructor still continues to emit offensive odours and we learn from Dr H Humphreys that on July 1st he had to keep his windows shut all day and night on account of "oily and gritty fumes blown down upon us by a northerly wind." The Misses Tapper who have before complained to the Council on the subject tell us the same story about July 1st. These ladies say that even after their doors and windows were closed "the sickening odour pervaded the whole house" The town council apparently argue that there is no noxious smell given off by the destructor Of municipalities it may be said with the Psalmist, "Noses have they but they smell not." In the good old days when Smithfield and its vicinity was a sink of cruelty—"dung, guts, and blood" and other horrors—it was proposed to do away with the cattle market This proposal met with bitter opposition from the City fathers, one of whom went so far as to say that the Smithfield smells were as refreshing as the seaside This remark inspired Leech to the drawing of an inimitable cartoon which appeared in *Punch*—we fancy in 1854—wherein the alderman and his family were depicted taking a summer holiday in Smithfield and saying, "How delicious the drains smell this morning" Possibly when the Torquay councillors do smell the destructor they will say the same thing We wish that they would send us a copy of Mr Davis's report. We have it on the authority of the mayor that there is nothing to keep back We learn from the "Torquay Directory" of July 2nd that 500 copies of the new "Pictorial" issued by the Torquay Directory Company have been obtained by the corporation for distribution throughout the country From this "Pictorial," a copy of which lies before us, we see that it is claimed for Torquay that at the present moment it stands pre-eminent for the perfection of its sanitary system. 'Nothing that science, skill, and money can achieve has been left undone the local authorities and sanitary staff are imbued with a deep sense of the importance of perfect sanitary arrangements and devote no little time, energy, skill, and constant supervision to maintain in a high state of efficiency everything bearing upon, or contributing to, the health of the people" Despite this, however, the average visitor will not be allured by the smells from the destructor which apparently envelop Torquay whenever there is a northerly wind.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND

THE sixty-first annual meeting of the Medico Psychological Association of Great Britain and Ireland will be held at the Medical Institution, Hope street, Liverpool, on Thursday and Friday, July 24th and 25th, under the presidency of Dr Joseph Wiglesworth. The annual meeting will commence at 11 A M on Thursday and will be preceded by meetings of the Educational Committee, the Rules Committee, the Parliamentary Committee, and the council, to be held between 9 and 10 A.M After the election of the officers and council eight candidates will be proposed for election as ordinary members, Dr Giovanni S B Estense of Rome will be proposed for election as a corresponding member, and Dr Sidney Coupland of London and Dr Edward N Brush of Towson, Maryland, U S A, will be proposed for election as honorary members At 2 P M. Dr Wiglesworth will deliver the presidential address, after which medals and prizes will be distributed. At 3 15 P M Mr Damer Harrisson will read a paper entitled "Some Remarks upon the Surgical Treatment of Insanity" At 4 P M Dr Charles A. Mercier will propose the following motion, upon which Mr Percy Becher, solicitor, of Bedford row, London, and others will speak "That in the opinion of this association further legislative measures are needed to protect the property of those who, without being certifiably insane, are yet, by reason of disorder of mind, unable to administer their affairs with ordinary prudence" The annual dinner will be held at the Adelphi Hotel, Liverpool, at 7 P M (tickets £1 1s, inclusive of wine) On Friday July 25th, at 10 A M, Dr F W Mott will read a paper entitled "Stimulus in Relation to Decay and Repair of the Nervous System." Professor C S Sherrington, Dr W B Warrington, and others will take part in the discussion Dr A W Campbell will give a lantern demonstration on Medullated Nerve fibres of the Cerebral Cortex. Dr David Orr will give a lantern demonstration on Nerve-cell and Medullated Fibre Changes in Acute Insanity At 2 P M Dr T S Clouston will introduce a discussion upon "The Possibility of Providing Suitable Means of Treatment for Incipient and Transient Mental Diseases in our Great General Hospitals," after which Dr C Hubert Bond will read a paper entitled "Medico-Psychological Statistics—the

---

[2] Loc. cit

Desirability of Correlation with a View to Collective Study " Dr A. R. Urquhart and Dr W Ford Robertson will read a clinical report on a case of Epilepsy Dr W R. Dawson will read notes on the Pathology of Diabetic Insanity The President and Mrs. Wiglesworth invite members to a garden party on Saturday July 26th, at the Rainhill Asylum, near Liverpool.

THE DISTRIBUTION OF PLAGUE

THE weekly return of the Director General of the Sanitary Department of Egypt shows that for the week ending June 29th there were 3 new cases admitted of which 1 occurred in a European. The deaths numbered 7 the recoveries 6, and 8 cases remained under treatment With respect to sanitary measures 14 230 rooms were disinfected and 3714 were limewashed 136 sacks of effects were disinfected and 1423 sacks of rubbish were burned. The number of rats killed and burned was 960

THE REGULATION OF THE SALE OF LIQUID DISINFECTANTS UNDER THE PHARMACY ACT

ACCORDING to a recent order of the Lords of the Privy Council liquid disinfectants are now to be included in the clause of the Pharmacy Act which relates to the dispensing and selling of poisons and liniments, embrocations and lotions containing poison. That is to say it is now required by the Pharmacy Act that liquid disinfectants shall be sent out in bottles rendered distinguishable by touch from ordinary medicine bottles, and that there shall be affixed to each such bottle (in addition to the name of the article and to any particular instructions for its use) a label giving notice that the contents of the bottle are not to be taken internally This sensible amendment is the result of a resolution of the Pharmaceutical Society made on May 28th 1902, the Privy Council consenting to it almost immediately It will be seen that the term liquid disinfectants will embrace a very great number of preparations.

THE POSTPONED PROCESSIONS AND THE HOSPITALS

THE sad and widespread disappointment which the postponement of His Majesty's Coronation inevitably occasioned was felt with peculiar weight by those hospitals the happy situation of which enabled them to offer a large number of seats for spectators. It will be readily understood that besides the natural joyfulness of the occasion an excellent opportunity was welcomed for adding to the funds—never too flourishing—of charitable institutions Considerable expense was incurred to render those who had bought seats at the hospitals comfortable for the day s sight-seeing and the disappointment which overwhelmed London was thus given an exceptional keenness in the cases to which we refer It is very pleasant, therefore to be able to record the generosity with which on the whole those who had purchased seats at the hospitals have acted. In the case of St. George s Hospital very many of the purchasers have refused to take back any of their money many others have accepted only part, and but a very small proportion have availed themselves of the offer of the hospital to refund the whole amount. It is fortunate that the return of Lord Kitchener provides St. George s Hospital with an opportunity that the authorities of the hospital have eagerly seized for repaying in some degree the generosity of the seatholders. Those who have presented to the hospital the full amount that they subscribed for Coronation seats are having seats placed at their disposal for Saturday s pageant and as far as possible all who contributed any of their money are to be similarly accommodated if they so wish.

WE understand that Sir Frederick Treves on the occasion of his being made a baronet will be described as Sir Frederick Treves of Dorchester and Sir Francis Laking on receiving the same honour, as Sir Francis Laking of Kensington Such designations are not, we believe territorial but are necessary as distinctive marks seeing that there may be baronets who happen to bear the same Christian and family names

THE annual meeting of Fellows of the Royal College of Surgeons of England was summoned for July 3rd but only five Fellows attended and as a quorum of 30 is required no meeting was held. The President remained in the theatre for 15 minutes before he could declare that the meeting would not take place. This is the sixth occasion on which no quorum has been present.

THE Epsom College annual prize distribution will take place on Founder's Day July 26th at 3 30 P M in the big schoolroom of the College, preceded at 3 P M. by a choral evensong in the College chapel The Right Rev the Lord Bishop of Winchester D D will give an address and distribute the chief prizes.

Looking Back.

FROM

THE LANCET, *SATURDAY, JULY 10*, 1824

ST THOMAS'S HOSPITAL.

An accident seldom met with was also brought in, and is now in George s ward The man in coming down stairs slipt his foot and in attempting to save himself he threw his trunk suddenly backwards, and felt something snap at his knee, and on recovering his footing he found he had no power over the leg He was carried to the Hospital and it appears that he has ruptured the tendon of the rectus the patella is in its situation its figure is perfect, but there is a hollow just above it, into which the finger readily sinks, and a defined firm surface can be felt just above the hollow but it has not the hardness of bone. The leg is secured just in the same way as in the fracture of the patella.

Dr ROBERT HONEYMAN a Physician, who died on the 21st ult. in Virginia, whither he emigrated from Scotland in 1774 has left the following bequest in his will dated in 1821 — I also give and bequeath to my son *a human rib* which will be found in a small trunk in my chest with my earnest request that he will carefully keep the said rib (*which is of James the Fifth King of Scotland*) and transmit it carefully to his descendants.

BIRTH.

At Martley in this county on the 9th of April Charlotte Hawlins a married woman about 36 years of age was delivered of a male child, totally without arms legs or thighs! The child is still living and appears healthy There is not to the present time the slightest appearance of the upper or lower extremities; but on the left side at the part where the thigh usually commences there is a little process in the shape of a finger consisting of two small bones united by ligaments, and covered with skin and cellular membrane; the projection has apparently muscles attached to it as it is constantly moved by the child when it cries or struggles It is nearly two inches long, thick at the base and runs to a point having a nail attached to it The expression of the countenance is not unpleasing The extraordinary appearance of this child (which in fact is a mere *torso*) cannot be conveyed by description *It is presumed* that there is no case on record at all parallel in the degree of defect.—The father is a labouring man between 60 and 70 years of age.—*Worcester Journal.*

THE LANCET

Special Analytical and Sanitary Commission

ON THE

IODO-BROMO SALINE WATERS OF SALSOMAGGIORE

History, Environment, and Climate

THE remarkable natural waters of Salsomaggiore were known to possess very definite therapeutic properties long before their exact chemistry was brought to light All that was known was that the waters were excessively saline and many times stronger in this respect than sea water, but soon it was clear that the marked therapeutic advantages which the water presented indicated something more than the presence of common salt. And chemical analysis has now established the fact that the Salsomaggiore waters possess a wealth of the rarer salines not approached by any other water in Europe. The bromides and iodides of magnesium and the chlorides of strontium and lithium exist in such tangible amounts that there can be no doubt that these contribute considerably to the therapeutic efficacy of the waters. The presence of such enormous quantities of dissolved salts, such as the chlorides of sodium and calcium, in the Salsomaggiore waters as shown by our analysis below renders them of course *antiseptic*, and doubtless to some extent definite therapeutic effects may be referable to a continuous antiseptic lavage In that case, however, it might be expected that all waters presenting a simple and similar composition would have the same action, and this to an extent is the case When, however, the composition is complex the therapeutic indications and applications at once widen And this is remarkably so with the waters of Salsomaggiore They not only contain rare salines over and above the ordinary chlorides of calcium and sodium but they are saturated with gaseous as well as liquid hydrocarbons, and these, as we shall show presently, contain impurities of a bituminous nature, and sulphur, an observation which may throw still further light on the excellent results gained in certain therapeutic applications

The Salsomaggiore waters were undoubtedly known to the Romans as salt springs and as such were regarded as a valuable asset It was not however, until 1839 that definite evidence of their therapeutic properties was gained Dr Berzieri established the value of the waters as a therapeutic agency of distinct merit by showing their favourable action in tuberculous disease, not then specifically recognised and his first case was one of caries of the bones of the foot This formed the starting point of the reputation of the Salsomaggiore waters which are employed *inter alia* with encouraging results in all cases of tuberculous lesions, whether of the bones, joints, or skin , in tuberculous enlargement of glands , and in other scrofulous manifestations But, as we shall point out a recent visit of our Commissioner to the place has demonstrated that the result of increasing experience has opened a far wider field of therapeutic usefulness for these waters—a fact which has put immense pressure to bear upon the resources of the baths and hotels in the village, a pressure which has led the authorities to provide an increased balneological equipment equal to growing needs and not in any degree inferior to that found in the well known European spas

Salsomaggiore is a village of some 2000 inhabitants, situated in the Emilian valley on the eastward side of the Appenine foothills in the province of Parma in North Italy It is only a few miles west of the main line of railway between Milan and Bologna The journey by light railway from the station on the main line, Borgo San Donnino, occupies about half an hour to Salsomaggiore Milan is distant about three hours' journey and the best trains stop at Borgo San Donnino during the season, which is from the beginning of April to the end of October The most suitable time for English visitors is, however the spring and the autumn, for in the months of July and August the weather is very hot. In the spring and autumn months the temperature is comfortable and the climatic conditions in general are genial Salsomaggiore is about 500 feet above the sea level and the surroundings are undulating and picturesque and tree and vegetable growth is very luxuriant. There are many interesting and charming localities in the environment of Salsomaggiore. Views may be obtained over the great blue Lombardy plain, stretching away to the Swiss Alps which can be seen plainly with their snowy tops beyond The air, though soft, is decidedly bracing The view given in Fig 1 was taken from a hill at the east end of the village, showing the Grand Hôtel des Thermes on the right, the Grand Hôtel de Milan and the Terme Magnaghi on the left, and other *alberghi* (hotels), the salt works, and the sanatorium in the distance. The Grand Hôtel des Thermes, which was completed in 1900, is nearly opposite the largest *stabilimento* There are, however, a number of *stabilimenti* The Terme Magnaghi are the most important and the best equipped, and they are situated close to the *Pozzo artesiano* (Magnaghi), the artesian well sunk on a piece of land adjoining the Grand Hotel which supplies both the *stabilimenti* and the baths of the hotel The Grand Hotel contains 300 rooms and is under the joint management of Mr Ritz of the Carlton Hotel, London, and Mr Pfyffer of the Grand Hôtel, Rome.

The Water supply

The water supply to the hotel, of which those in the village who choose may avail themselves, is derived from a deep cutting in the chalk of the hills to the west of Salsomaggiore, a few miles away In Fig 1 the road leading up to the reservoir will be seen Great care is exercised to keep this water from contaminating influences Our Commissioner secured several samples of this water for analysis and for that purpose drew the water from a supply tap There are two sources of water supply but the character and quality of both waters are the same. As will be seen from the results of analysis the water supply is of excellent quality and character It is of a very high degree of purity with not a trace of organic impurity Indeed, there is a singular and complete absence of nitrogenous matter in any form—practically no nitrates and no ammonia saline, or albuminoid, only a little carbonate and sulphate of lime The colour is a pure transparent bluish green The results of analysis were as follows —

Analysis of Salsomaggiore Water supply

Appearance	Bright and without sediment.
Colour in 2-feet tube	Bluish green, like distilled water
Taste	None.
Smell	None
Reaction	Slightly alkaline
Free ammonia	None.
Albuminoid ammonia	None
Nitrogen in nitrates and nitrites	Trace.
Chlorine in chlorides	0 56 grain per gallon.
Equal to common salt	0 91 grain ,,
Phosphates	Slight trace
Total hardness	19 68 grains per gallon
Permanent hardness	5 50 ,, ,,
Temporary	14 18 ,, ,,
Oxygen absorbed in one hour	Inappreciable

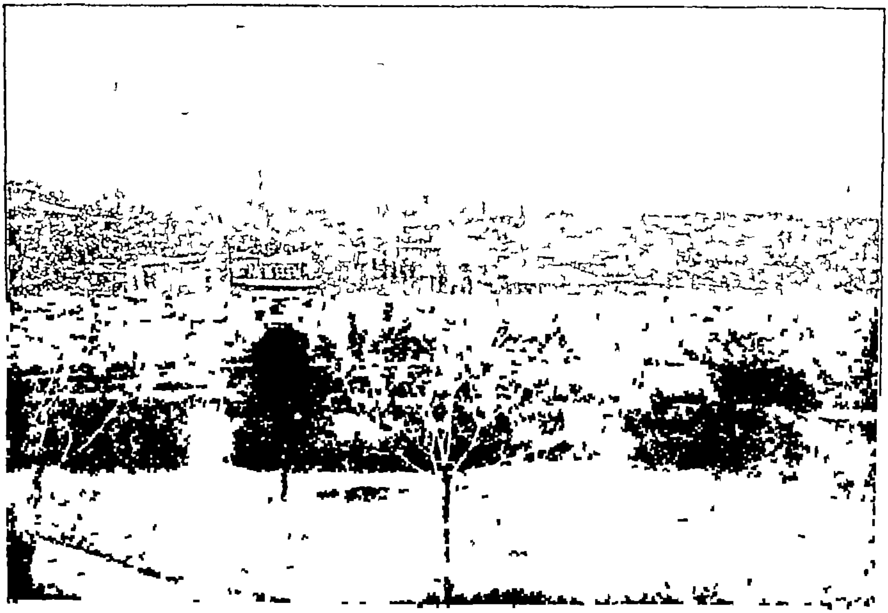
The water supply of Salsomaggiore is abundant and its striking purity as displayed in the analysis is a matter for congratulation It ranks amongst the purest potable waters known

The Bathing Establishments and Balneo therapeutic Methods.

As already stated, amongst the chief *stabilimenti* are the Old, the New, and the Terme Magnaghi, which, being the last to be constructed, are the most modern in design as they are the most commodious in the village. They are fitted throughout with the electric light, so the current may be used for many other purposes and as an adjunct to hydro therapy There are an x ray room, a high frequency apparatus, and an apparatus for the application of the ultra violet rays. Photo therapy, electro-therapy, hydrotherapy, and, as we shall point out presently, mechanotherapy are thus associated. A view of the establishment, which is at the present time undergoing considerable further enlargement, is afforded in Fig 1. A tall shaft which will be noticed on the left serves to locate it.

This chimney is connected with machinery employed for raising steam, for pumping water for working the inhalation and spray apparatus and for other purposes It is not a little remarkable to find in a mere village remote in the Alps a commodious bathing establishment containing all the modern scientific appliances used in balneo-therapy and to find also in practice the most modern methods of affording supplementary treatment. Members of the medical and surgical staff, both English and Italian are constantly in attendance Rooms are provided and are fitted with all the modern surgical appliances for minor operations or examinations. There is adequate provision for massage, skilled masseurs and masseuses being retained for the purpose. The comfort of the patient has been very carefully studied in all particulars and there is a lift to every floor A staff of skilled attendants is kept. The baths are of special composition, resisting the corrosive action of the water and most minute antiseptic precautions are taken to insure the cleanliness of the bath and of the linen used in connexion therewith for each bather The bath is washed out with creolin for each occupant and all the linen and towels are sterilised in a steam disinfector and washed also in a weak solution of corrosive sublimate. Similar antiseptic precautions are taken with respect to the walls and floors of the building and altogether an admirable regard as to conducting the establishment on strict hygienic principles is shown

FIG 1.



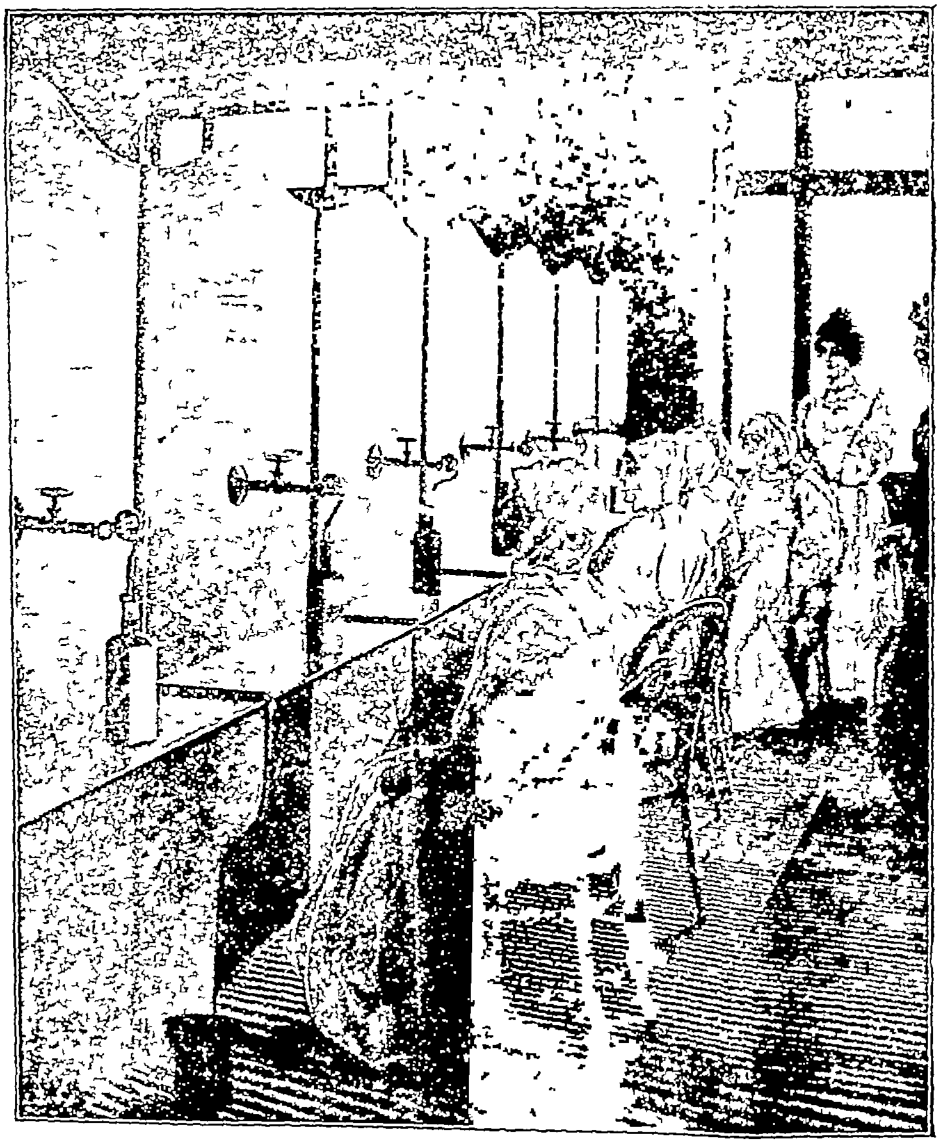
View of Salsomaggiore looking to the West

The course consists of a daily bath in the natural mineral water for about three weeks according to the indications of the patient. Some may take a bath every day with comfort, while in other cases it is found that the bath must be taken on alternate days or suspended for a time. This course becomes necessary owing to the marked therapeutic action of the water Again an excellent system is adopted by which the patient is gradually introduced to the full strength of the water This method of educating so to speak the patient to the effects of the water is one that must be generally approved and one which is obviously sound in principle. With such a wealth of powerful salines as are contained in the Salsomaggiore waters a system of graduation is imperative. Undoubtedly mischief might be done by disregarding this graduated system of administration The duration of the bath is from a quarter of an hour to three-quarters of an hour and the temperature varies from about 34° to 39° C. As a rule the density of the saline bath seldom exceeds 1096, and as the density of the natural water is according to our examination made on the spot, 1120 it is a simple matter to obtain the requisite lower density The composition of the bath may be varied however in many ways—for example, the *acqua madre* or mother liquor may be used in special cases in which it is considered that a richer proportion of lithium chloride or of the iodide and the bromide is desirable. This concentrated liquor is obtained by the evaporation of Salsomaggiore water in large flat basins, the salt being removed as it crystallises By proceeding in this way the rarer salines which are more soluble than common salt, are concentrated.

In addition to a very complete equipment of baths the Magnaghi establishment contains also rooms set apart for *providing means of inhaling the waters—a system* which forms a novel and very important feature of the treatment at Salsomaggiore For the purpose of inhalation two methods are employed In the first the patient sits in front of an atomiser operated by steam power projecting the mineral water in a fine vapour from a given quantity of the water contained in a sterilised bottle below The system will be understood from Fig 2 and is known as Siegle and Pirey's system. Here again the water is used in different strengths according to the needs of the patient and this system of graduation is carefully adhered to throughout the establishment so far as individual cases are concerned. It is noteworthy and we shall return to this point, that in the inhalation room a smell pervades the atmosphere recalling that of iodoform There is no doubt that small quantities of free iodine and perhaps free bromine *exist under the conditions of the system. At any rate, light* and air or both liberate iodine from Salsomaggiore water For the purpose of inhalation by Siegle and Pirey's system the *acqua madre* is employed of a specific gravity varying from 1014 to 1057 As will be seen from the illustration (Fig 2) the patient wrapped in a waterproof cloak i seated in front of the spray producer and bottle. The patien inspires the fine vapour for from 10 to 15 or even 30 minutes Presently will be described the therapeutic indications of this particular form of inhalation. Suffice it now to add that this method, coupled with another which we will next discuss, is assuming great importance, constituting a departure in the administration of natural mineral waters which is yielding very interesting results and deserving of special attention.

In Jünnigen and Beiselen's system the spray is exceedingly fine, like mist, and is made to occupy the whole of the space of a room large enough to admit of exercise being taken, if need be, at the same time. This system becomes intelligible from an inspection of Fig 3, in which the patients are shown in a large room muffled in white *peignoirs* and their heads wrapped in white cloths, walking about, sitting down, talking, or it may be carrying out gymnastic exercise, such as riding a stationary bicycle or taking exercise on a mechanical horse, or pulling the sculls of a mechanical rowing-boat. Exercise in increasing the circulation promotes the absorption of the saline vapour In this case the natural Salso water at a density of 1057 is pulverised by a special apparatus shown at the upper part of the illustration a little to the left The odour in this room is strongly suggestive of an iodo organic compound as well as oily So encouraging in many cases are the results of treatment by this system that an entirely new building is being constructed for the purpose which will afford considerably greater accommodation This system is increasing in favour

FIG 2



Siegle and Piroy's system of inhalation

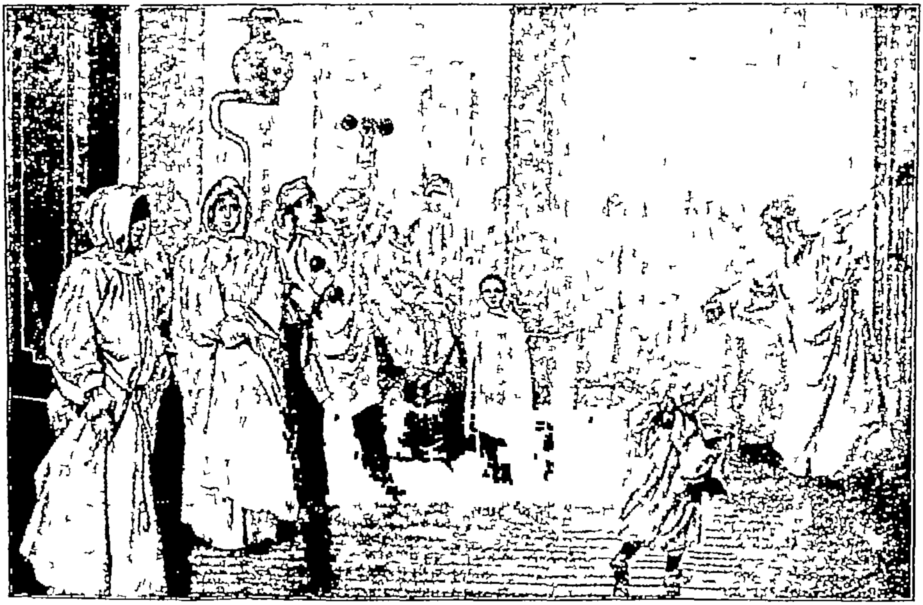
The Pozzi (Wells) at Salsomaggiore

There are quite a number of wells (*pozzi*) in Salsomaggiore but they obviously tap one origin, for the composition of the water is practically the same from whatever well it is drawn Formerly, and at the time when the waters were only valued for the common salt which they contained which was crystallised out by a process of evaporation and sold for ordinary purposes, the water was pumped from shallow wells, but now some *pozzi* are over 2000 feet in depth The Pozzo Artesiano Magnaghi is a deep well which supplies the Magnaghi establishment and the Grand Hôtel des Thermes As already pointed out, the wells are remarkable in yielding at the same time gas, oil, and mineral water At times there is a considerable disturbance of the water owing to the sudden discharge of gaseous hydrocarbons, the chief of which is methane So great is this disturbance on occasions that a tall wooden shaft or canopy is erected over the well to avoid any unpleasant consequences of overflow arising from the inflammable nature of the gas or the oil. In Fig 4 is depicted the Pozzo Artesiano Magnaghi over which a shed has been constructed to cover the pumping machinery and the reservoirs The mouth of the well itself will be seen at the end of the shed with a ladder resting against the wall of the well. The pump, though at present of a somewhat archaic description, the arm on the crank being made of wood, answers its purpose well. The pump is driven by a gas-engine shown at the right of the picture, the gas being derived from the well itself. On the floor of the shed will be noticed a square area of illuminated ground which is the light coming from the shaft over the well already described. Viewed from the outside this shaft resembles in appearance the hop cones seen in Kent.

The Nature of the Oil and Gas

The gas escapes by a pipe at the top of the well directly into a gas-holder whence it is distributed without any purification whatever for lighting and heating purposes. It contains two-thirds methane and a third ethane with heavy hydrocarbons and carbonic acid gas. The amount of natural gas evolved is sufficient to supply the street lighting of the village and to drive gas-engines where power is required. A litre of the water holds about 20 cubic centimetres of this gas in solution but the ratio of methane to carbonic acid gas is about equal volumes. The water and oil flow together into a small tank where the latter is separated by the simple expedient of decanting Of course there is a great difference between the specific gravity of the water and the oil. According to our observations the specific gravity of the oil is 0 840 so that it rapidly rises to the surface. The oil has exactly the smell of common paraffin or light petroleum. *By transmitted light it has a clear dark brown colour* but by reflected light it exhibits a marked green fluorescence very like that of uranine. We have submitted this oil to fractional distillation. It first shows signs of boiling at 150° C. and fully one-half of the oil distils below 200° C. The rest showed no sign of distilling at 250° C. and at that point notable quantities of sulphuretted hydrogen were evolved The oil contains bituminous bodies and sulphur but apparently neither iodine nor bromine. We found however as might be expected, *that it readily absorbs* iodine and bromine. This observation is of some importance, for though we failed to find any appreciable quantity of iodo- or bromo-oils present yet on exposing the mixture as it comes from the well to light and air iodine is liberated and afterwards in part absorbed by the petroleum. Again when the water is reduced to an exceedingly fine spray as in the inhalation room in the presence of light and air iodine is also liberated, as demonstrated in our experiment and since the natural water contains some oil there is no doubt that traces of iodo-oil are formed. We found further that when iodine was added to the natural oil of Salsomaggiore and mixed with water and atomised the resulting spray had identically *the same iodous smell as that which characterises the inhalation* room at the Terme Magnaghi. This interesting experiment has an important bearing on the therapeutic effect of natural Salsomaggiore water as administered in the form of a respirable spray Again, the presence of sulphur in the oil as determined by our experiments is probably another important therapeutic factor

FIG 3.



Jännigen and Beiselen's system of inhalation.

The Water of Salsomaggiore and its Analysis

The water is brownish in colour and greasy looking and smells unmistakeably of common paraffin oil. Its brown turbidity is due to the separation of ferric oxide. The temperature of the water as it issues from the well is, according to our observations, exactly 20 5° C. *and its density* at 15 5° C. 1120 For the purpose of analysis samples were secured and sealed on the spot by our Commissioner and despatched to THE LANCET Laboratory Subsequently a consideration of the results gained has led to the probability of the amount and kind of salts present being as follows —

The Analysis of Salsomaggiore Natural Mineral Water

Sodium chloride	146 2940	grammes per litre.
Calcium chloride	16 2376	„ „
Magnesium chloride	5 0861	
Ammonium chloride	0 6000	
Strontium chloride	0 5000	„
Lithium chloride	0 6399	
Strontium sulphate	0 4868	
Magnesium bromide	0 3022	
Magnesium iodide	0 0664	„
Ferric oxide	0 1000	
Total mineral constituents	169 3129	grammes per litre

Spectroscopic examination gave a pretty array of luminous bands, the presence of sodium calcium strontium and lithium being easily demonstrated in this way The spectrum of the rarer elements was more marked with the *acqua madre* or the concentrated water The striking features of this analysis are the important amounts of bromine, iodine, strontium, lithium, and ammonium salts, the presence of which in such remarkable quantity marks the waters of Salsomaggiore from other saline waters of the same class The lithium chloride thus exceeds over 40 grains per gallon or five grains per pint, while the bromine is no less than nearly 20 grains per gallon and the iodine amounts to over four grains per gallon It is doubtful whether other mineral waters show such a richness of these comparatively rare constituents The proportion of certain of these saline constituents is, of course, raised by concentration, while the common salt is lowered on account of its separation and removal by crystallisation on evaporation. The process of concentration is carried on at the salt works at the lower end of the village and not far from the railway station. The actual site is marked in the illustration (Fig 1) by a chimney shaft which will be seen just below a far off hill in the middle of the picture The water is concentrated to various degrees of density so as to leave a wide choice to the physician as to the strength which he deems it desirable to administer to the patient. *Acqua madre* is contained in sterilised bottles of the description shown on the bench in Fig 2 To facilitate the separation of the iron and to remove also some of the calcium and magnesium salts carbonate of soda is sometimes added to the natural water before concentration If a sufficient quantity of carbonate of soda is added the calcium salts can be almost completely removed The water would then contain in solution common salt with the rarer salines Common salt being crystallised by evaporation and removed another liquor is obtained very rich indeed in lithium, iodine, and bromine The strongest *acqua madre*, according to our examination, exhibits a density of 1270 Unlike the natural mineral water, it is bright and clear and without sediment and does not contain iron or any sulphate. Our complete analysis of *acqua madre* was as follows —

The Analysis of "Acqua Madre"

Sodium chloride	45 8581	grammes	per litre
Calcium chloride	221 5560	,,	,,
Magnesium chloride	73 7200	,,	,,
Strontium chloride	11 5500	,,	,,
Ammonium chloride	2 0972	,,	,,
Lithium chloride	8 7853	,,	,,
Magnesium iodide	1 0008	,,	,,
Magnesium bromide	4 8355	,,	,,
Sulphate (probably of strontium)	traces		
Ferric oxide	*Nil*		
Total saline constituents	369 4029	grammes	per litre

It will be seen from this analysis that the constituents, except of course the common salt which is removed by crystallisation, bear practically the same ratio to each other as in the natural mineral water, and since these occur in about 15 times the quantity the concentration amounts, in this instance, to the reduction of 15 volumes of natural mineral water to one volume *Acqua madre* is exceedingly rich in lithium, bromine, and iodine. Expressed in English equivalents the lithium chloride amounts to no less than 614 grains per gallon or nearly 80 grains per pint, and the bromine to 294 grains per gallon or nearly 37 grains per pint, and the iodine to 64 grains per gallon or eight grains per pint. There is no mother liquor derived from a natural mineral water which in our knowledge is richer in the rarer salts than this, and certainly no other water shows a more interesting composition from a therapeutical point of view than the natural waters of Salsomaggiore or presents such an interesting chemistry

The Therapeutics of Salsomaggiore Water and Indications

It is not surprising, in view of the chemistry of the Salsomaggiore water as revealed in the foregoing analyses, that it is possible to open a wide field of therapeutic application and usefulness Chemistry, however, does not always throw a sure and certain light on the action of certain waters, indeed, there are notorious instances in which very little clue is afforded at all by the facts of chemical composition In Salsomaggiore water, however, the presence of very definite salts and substances which are of known value therapeutically is readily established by chemical analysis How far the action of these substances is modified or accentuated by the particular way in which they are grouped in a natural mineral water is difficult to determine We can only rest on the actual evidence of clinical experience and in many instances that is often problematical, for good results are often obtained when not anticipated and *vice versâ* unsatisfactory results are sometimes obtained when good might reasonably have been entertained Balneo therapy is not so completely understood as to enable us to formulate exactly why certain conditions are relieved by this that, and the other water

A systematic and practical study of the action of the Salsomaggiore waters administered either in the form of a bath or inhalation was begun several years ago by an efficient medical staff. We may record the experiences that have been so far gained, and we are indebted to Dr G Sandison Brock of Rome, who has had ample opportunity of studying the action of the waters and of devoting special attention to the large number of cases constantly under treatment at Salsomaggiore, for the substance of the clinical observations that follow We have already referred to the fact that the first recorded case of the therapeutic application of Salsomaggiore waters was that in which Dr Berzieri in 1839 was induced to submit a patient to treatment who was suffering from caries of the bones of the foot, which was no doubt tuberculous in origin It is freely stated that Dr Berzieri's idea was that Salsomaggiore water might be substituted for sea water The result was a striking success and the reputation of the waters in regard to their favourable action in cases of tuberculous lesions, in tuberculous enlargement of glands, or in other scrofulous manifestations steadily spread until at the present time Salsomaggiore enjoys an almost unique position in regard to the benign effects of its waters in cases of this class It is interesting in this connexion to point out that the efficacy of the treatment became so well known and so firmly established that the various communes in Italy, at their own cost, have been accustomed to send parties of poor patients for treatment every three weeks to the sanatorium The result has evidently been so encouraging that patients have presented themselves again of their own accord as relapses of their old maladies or fresh symptoms have led them once more to seek relief Of course, change of air and environment must be ever factors in balneo therapy, but these cases must be considered as amongst the most promising of those indicated for the Salsomaggiore treatment.

The alterative and absorbent effects of the water which are at the root of the successful treatment of scrofulous affections soon suggested an extension of the use of the waters to all affections where in connexion with some localised morbid process there existed open sores or sinuses or inflammatory swellings, and especially exudations. Thus might be expected to yield to treatment with the Salsomaggiore waters those maladies which are due to what is now recognised as the result of infection by specific germs other than that of tubercle, especially in their later or chronic stages when the acute inflammatory period has disappeared Naturally in this category come the later stages of syphilis, both the secondary manifestations in skin, mucous membrane, and periosteum, and the tertiary effects in bone and the organs, *gummata*, *necrosis*, &c., and also the sequelæ of gonococcic infection, whether in the form of inflammatory infections of the genital organs as in orchitis, endo-, para and peri *metritis*, *salpingitis*, *oöphoritis*, or the general rheumatoid arthritis and infective lesions of serous membranes often seen as sequelæ of the gonorrhœal infection. Under special circumstances the irrigation of the uterine cavities with the water of carefully graduated strength is valuable

As to the acute stages of inflammatory diseases it is stated that in the experience of some the Salso waters are contraindicated Dr Brock, however, records a case of gout which yielded so favourably to treatment as to give an opposite inference The acute condition was, he states, distinctly relieved by the baths and acute rheumatism has been treated with similar success It is probable that by graduating the baths in the way which we have already described the Salsomaggiore treatment would be helpful and not harmful. It is agreed, however, that the acute stage once over great benefit is derived in the treatment of the sequelæ or of any of the results of inflammation that may have persisted In this regard might be mentioned the after effects of appendicitis and peritoneal inflammations attended, or followed by, exudations, chronic pleurisies, synovitis, arthritic troubles, or bony enlargements following fractures, in fact, any chronic inflammatory process accompanied by pain, swelling, or deformity and stiffness which call for the soothing, stimulating, or absorbent effects of the waters or application of the mud deposited from them. The mud, we should add, is a soft clay deposit found in the reservoirs. It has a marked soothing effect. The mud is saturated with the salines of the water and contains also an appreciable amount of the petroleums. It is greasy to touch. When heated and applied daily after the manner of a poultice for from 20 minutes to half an hour round the affected part it allays pain, reduces swelling, and renders supple stiffened muscles and ligaments. In this way it has been employed with excellent results for chronically inflamed joints, enlarged glands, and painful periosteal swellings and relief is also obtained by its application in painful gouty and rheumatic affections of nerves, especially where there is a localised neuritis.

The baths give very satisfactory results in arthritis consequent upon acute rheumatism or in relapses of that disease and the same is true, though perhaps less emphatically so, in gouty affections. In these cases the baths exercise a soothing and absorbent effect, increasing tissue metabolism and the activity of the secretions and excretions and thus enabling the system to dispose more readily of waste products through the skin, the lungs, and the kidneys. Some interesting observations on these points have been made by Dr. Luigi Zoja in his "Studi Preliminari sull' Azione dei Bagni Salsi (Acque di Salsomaggiore)." Dr. Zoja has also made some observations on the cutaneous absorption of iodides in the baths and has contributed also a further interesting study on the reduction of the body weight by treatment with Salsomaggiore waters.

FIG. 4.

The pozzo artesiano (Magnaghi).

In view of the stimulating and purifying action of the Salsomaggiore waters it is not surprising to find that they are beneficial in neurasthenic and anæmic cases even without the simultaneous employment of the usual hæmatinics. Thus it happens that incidental complaints are relieved in patients who had presented themselves for treatment for some other malady. In one instance, a case of rheumatism, while much benefit was derived and pains and stiffness ceased by the use of the baths and inhalations, the patient noticed that the loss of hair which she had been steadily sustaining for some time suddenly stopped. As we have pointed out, the waters at Salsomaggiore are saturated with gaseous and liquid hydrocarbons and these latter contain sulphur in organic combination. Although the benefit derived was probably of a constitutional origin, yet it is just possible that these interesting facts were contributory to the relief. Other incidental cases of interest are those in which women have been cured of sterility although they had come for the Salsomaggiore treatment for the relief of other ailments; but here, of course, the *modus operandi* may differ widely in different cases according to the cause of the condition. Functional disorders such as constipation, irregularity of the catamenia, &c., have been noticed to disappear and appetite to increase and the ability to sleep to return.

The Inhalation of Salsomaggiore Water Reduced to Spray.

Special attention has already been directed to a somewhat new departure in balneo-therapeutic practice, consisting in the application of the water in the form of inhalation, a method which is pursued with considerable success at Salsomaggiore. Indeed, the inhalations at Salsomaggiore form a very important and interesting feature in the treatment and have proved a most valuable adjunct to the ordinary course of waters. We have already described the two systems of inhalation employed. In one case a spray is produced for the throat passages and in the other case the space of a room is filled with an exceedingly fine mist of the natural water. The patients, in fact, live for the moment in a Salso fog, inhaling the water in the form of vapour and exercising themselves, it may be, in order to gain the greatest advantage, for with increased circulation the absorption is speedy. There is good reason for concluding that the various salines in the vapour are readily absorbed by the mucous membranes. The use of these inhalations is, at any rate, becoming very general amongst bathers. There seems to be little doubt that during a prolonged stay in the inhalation room the salines, including iodine and bromine and probably traces of halogen organo-bodies derived from the oil, actually enter the blood and subsequently exercise a distinct influence upon morbid processes in the body. The inhalation method is thus a rapid and effectual means of *conveying* the therapeutic properties of the natural water At any rate, it is certain that by direct contact of the waters, whether by a spray or by means of the pulveriser of the inhalation room, excellent therapeutic results are obtained in local affections of the respiratory mucous membrane. Amongst respiratory affections thus frequently treated at Salsomaggiore with the most favourable results are coryza, chronic rhinitis (both the hypertrophic form and that accompanied by atrophy and the ozena-producing organism), chronic pharyngitis (especially the granular type), and laryngitis The irritation of the mucous membrane is soothed, congestion and swelling are reduced, and tough inspissated mucus is liquefied or loosened and a natural healthy condition of the moist surfaces is gradually induced. When the lower part of the respiratory tract is involved, as in chronic bronchitis and bronchial asthma, a prolonged stay in the inhalation room is frequently productive of good.

Summary

To sum up, Italy possesses a wealth of natural mineral and gaseous waters, but none are more remarkable than the waters of Salsomaggiore These are unique, not only in containing an unusual amount of the rarer salines such as the chlorides of lithium and strontium and the iodide and bromide of magnesium, but also gaseous and liquid hydrocarbons It is well known how often the therapeutic efficacy of a given element is increased by being associated with organic groups. Mention need only be made of the organic compounds, such as lecithin and glycero-phosphoric acid, containing phosphorus, of thyroidin containing iodine in organic association, of the cacodyls containing arsenic, and the hæmoglobin derivatives, and the albuminates containing iron Undoubtedly the organic association of iodine bromine, and other inorganic elements in Salsomaggiore water is contributory to a very important extent to the remarkable successes which are gained in the treatment of so many maladies at this favoured health resort The natural waters of Salsomaggiore are sharply distinguished from other natural mineral waters in presenting this organic association, and, moreover, they possess a degree of *mineralisation*, including the salts of rare alkalies, not exceeded by any other water This is shown in the analyses which we have made, which, as far as we know, are exhaustive. We have demonstrated that in contact with air and light Salsomaggiore water yields up some of its iodine in the free state and that the element so liberated is in part absorbed by the oils forming an iodinated compound with marked iodous odours which recall the iodoform series and which it is reasonable to suppose is an important factor in treatment especially by the method of inhalation We believe that we are the first to direct attention to this fact and also to the existence of an important amount of sulphur in the oil.

It may be added that the analyses made in THE LANCET Laboratory confirm in regard to the main points the analyses made in 1899 by Professor Nasini and Professor F Anderlini of the chemical laboratories of Padua University The water when fresh from the well *does not* contain any appreciable amount of free iodine or iodinated oil, but both are found after it has been in intimate contact with air and light. The water is constant in chemical composition and this composition indicates a wide field of therapeutic efficiency—a field which is still open for further exploration. Very important clinical evidence has, however, been gained which has established the value of the water in well-known and prevalent morbid conditions. These have been pointed out.

We have ascertained, and have placed the analysis here on record, that the water supply of Salsomaggiore is remarkable for its purity and excellent steps are taken to protect this purity Moreover, a factor of the utmost moment in balneotherapy, Salsomaggiore has a charming environment and a pure and bracing air The comfort of the patient is provided for in a number of excellently appointed hotels, and the course of waters is enlivened by amusements of all sorts. There are a theatre, a *café chantant*, and a music room, and outdoor and indoor sports and pastimes are encouraged. Our Commissioner has been impressed with what he has seen at this rapidly rising hydropathic resort, and it is satisfactory to be able to state that the authorities have striven hard to place their *stabilimenti* on a thoroughly sound and scientific basis, consistent with the requirements of a locality in which great numbers every year seek to regain health and vigour by the treatment. So well directed have these efforts been, and so high is the standard of balneo-therapeutic practice adopted there, that Salsomaggiore bids fair to take a well merited place in the front rank of European health resorts

ROYAL COLLEGE OF PHYSICIANS OF LONDON

AN extraordinary meeting of the Comitia was held on July 4th, Sir W S CHURCH, Bart., K C B, the President, being in the chair

The PRESIDENT announced that after paying expenses connected with preparations for viewing the procession in connexion with the Coronation, which had unfortunately been postponed, there remained a balance to the Fellows of £122 13*s* 6*d* This sum he suggested should be put aside as a nucleus around which he felt sure a fund would speedily accumulate and which should be devoted to obtaining a portrait of the King This would be an appropriate way of commemorating an exceptional event and also the connexion of His Majesty with the College This was formally proposed and seconded by Sir JOSEPH FAYRER, Bart., K.C.S.I., and Dr F W PAVY and was carried unanimously

A letter was read from the Royal College of Surgeons of England adopting with some slight alterations the scheme of cancer research This was adopted as modified and it was moved by Dr NORMAN MOORE and seconded by Dr FREDERICK TAYLOR that the College give the instructions recommended for the immediate nomination of the members of an executive and general committee to carry out the scheme.

A report was received from the Special Conjoint Finance Committee, dated June 30th, on the arrangements for the occupation of part of the laboratories by the Army Medical Department for three years at an annual rent of £1050. This was adopted

A letter was read from the Dowager Lady Jenner conveying to the College, according to the wish of the late Sir William Jenner, a silver vase presented to him by His late Royal Highness the Duke of Albany Sir DYCE DUCKWORTH, seconded by Dr WHIPHAM, moved that the gift be gratefully received and that the thanks of the College be returned to the donor

Communications were received from the Royal College of Surgeons of England reporting certain proceedings of the Council on May 8th and also on June 18th and conveying an invitation to the College to join them in appointing a committee to decide whether any practicable scheme of common examinations can be arranged with the University of London for the degree of M B of the University and the diplomas of L R.C P Lond. and M R.C S Eng Dr LIVEING moved, and Dr WHIPHAM seconded, that these be received and entered on the minutes. There was some discussion on this subject and the committee nominated to confer with nominees of the Royal College of Surgeons and report to the Comitia were Dr G V Poore, Dr P H Pye-Smith, Dr T Clifford Allbutt, Dr Norman Moore, Dr W H Allchin, Dr Frederick Taylor, Dr J K. Fowler, and Dr F J Smith

Reports were received dated June 2nd and 9th from the Committee of Management. They included (1) the revision of the list of recognised institutions for instruction in chemistry, physics, and practical chemistry, (2) the recognition of science institutions, (3) the proposed tramway on the Victoria Embankment, and (4) the revised regulations of the University of London in regard to matriculation In connexion with this matter the committee recommended following the lead of the University in preliminary examinations

A report from the Laboratories Committee on the general and bacteriological work was received and adopted, as was also the quarterly report of the examiners on the April examinations The enactment for the second time of a by law to admit two Members to the Fellowship *in absentiâ* was agreed to

---

WE are asked to draw attention to a change of title in the *Nursing Record* which will now be issued as the *British Journal of Nursing, with which is incorporated the Nursing Record*

YELLOW FEVER IN EUROPE

THERE has just arrived from Washington a fairly extensive report issued by the United States Marine Hospital Service of the Treasury Department on yellow fever in France, Italy Great Britain and Austria. It is a report upon which it is safe to say that much labour has been spent, for not only does the official who is responsible for its authorship—Dr J M. Eager of the Marine Hospital Service—devote his researches to the whole of the last century but there is a bibliography of books issued during the same period. Curiously enough, not a single American work is included in this list.

The earliest account we have of yellow fever in Europe is a case that is noted of importation of this disease at La Rochelle in the middle of the year 1700. Mention of this is to be found in a history of La Rochelle by Arcere published in 1756, but nothing can be got in the way of corroboration of this report. This, as we have said, is the earliest reported case of yellow fever in Europe, and the first authentic record comes also from France the date of the outbreak being 1802. The French fleet was the means of conveying *the pestilence to its own country* for when five vessels of the line commanded by Admiral de Joyeuse came into the roads from San Domingo it was the Admiral's unpleasing duty to notify that among the crews of his small fleet 42 persons were in the active stages of the fever and there were an equal number of convalescents. Of the sick crew who were all disembarked at the lazaretto at Tiberon, 32 died. Luckily it was well into the autumn and apart from the Customs officials some of whom had been on board one of the vessels the *Tourville* no mortality was reported ashore, a circumstance which is probably due to the fact that at Brest were several medical men who had been in the West Indies who insisted on the strongest sanitary measures being taken. The next outbreak of yellow fever in France was traceable to the epidemic which broke out in Spain, the date of both being 1821. What might have been a very serious epidemic for Marseilles was only averted through the fact that the famous Professor Palloni, who had been through the very bad epidemic of 1804 at Leghorn, was in Marseilles at the time and so prompt and thorough were the precautions upon which he insisted that the deaths, in spite of the big trade between Barcelona and Marseilles, were comparatively few Passing by the minor epidemic of 1839 at Brest we come to what Dr Eager calls the only important epidemic that ever broke out in France. It occurred at Saint Nazaire. Melier who carefully observed and recorded the epidemic, concludes that it was determined by mosquitoes infected at Havana and carried to France in the hold of a vessel. There are several interesting data to be noted in connexion with this case. The first is that yellow fever was noticed on the ship (the *Anna Maria*, with a crew of 16) 18 days after leaving Havana. She had been delayed by head winds and had to drift about the Straits of Florida for some time. Two seamen were taken ill *simultaneously* and died *within* a few hours of each other on the fifth day of their illness. At the time of their death there were seven other persons including the captain, down with yellow fever but quinine and cathartics cured them. In the whole ship there were nine cases of sickness and two deaths and 20 days after the last death the ship entered the port of Saint Nazaire. As no case of sickness had been noted for 10 days she was at once given *pratique*

Then the epidemic started. Two boats that were lying near the *Anna Maria* lost men the inception of the epidemic being seven days after the *Anna Maria* entered the port. One of the two boats already mentioned had sailed for Indret—a place 25 miles above Saint Nazaire—and it was there that the attack broke out. On the same day or eight days after the arrival from Havana, the first officer of the *Anna Maria* himself was laid low he died in 60 hours. Five stevedores who had been handling the *Anna Maria's cargo died in four* days a harbour master who had been 260 metres away from the boat or anyone connected with it all the time fell ill and several of the inhabitants also got the disease, mostly with fatal results. Of all the boats anchored near the ill fated *Anna Maria* not one escaped contagion. Indeed, speaking of vessels, the *Anna Maria* infected several, of which there were 40 cases of yellow fever and 23 deaths. And following this epidemic there were reports of the importation of the fever to French Mediterranean ports and also ports on the west and north. Fortunately there was no diffusion of the disease.

The outbreak of yellow fever at Leghorn in 1804 has already been referred to above. Strange to say a vessel named the *Anna Maria* was also on this occasion the means of bringing the scourge to Europe At that time the population of Leghorn was 60 000 of whom no less than 7000 fled to Pisa. How many of those that remained died from the fever it is difficult to say but the number must have been very considerable. Lacoste estimates it at no less than 1900 Coppie says it was 1500 and Palloni says it was 700 What is certain is that, curiously enough, the mortality was highest in the November of the year the fourth and penultimate month of the epidemic.

England has happily been practically free from this awful scourge. Dr Eager is able to give five well authenticated instances of outbreaks of yellow fever in English ports during the past century They were as follows, put quite briefly 1817 Liverpool cotton brig from America, outbreak confined to crew, no deaths. 1852, Southampton a steamer from Saint Thomas 14 cases seven deaths. 1857 Southampton, the same steamship that was suspected of having been the cause of a very severe epidemic at Lisbon entered the harbour, a *few cases of yellow fever no deaths* 1864 Southampton again, no full details. 1865 Swansea, boat from Santiago de Cuba, 15 deaths amongst the crew mortality on shore *nil*.

The bibliography at the end of the report, mentioned already is singularly incomplete but interesting It includes books published over the period 1789–1901 the works are mostly in Spanish or as in the fashion of the earlier days, in Latin The only book in our own tongue was published in 1804 it is by Valerio Arditi

ROYAL COLLEGE OF SURGEONS OF ENGLAND

AN extraordinary meeting of the Council was held on July 2nd Sir HENRY G HOWSE, the President, being in the chair

The following resolution was passed —

> The Council hereby offer their hearty congratulations to Sir Henry G Howse President, and Sir Alfred Cooper on being knighted by His Majesty and to Sir Frederick Treves on having received the honour of a baronetcy

On the recommendation of the Committee of Management it was resolved to lease to the Army Medical Department some rooms at the Examination Hall for the purpose of a medical school

It was resolved that an examination in Parts I and III (Chemistry and Biology) of the First Examination of the Conjoint Examining Board shall be held at some provincial centre as well as in London and a scheme was approved for this purpose. The first examination will be held in January next.

The following Cancer Research Scheme was approved and it has since received the approval of the Royal College of Physicians of London —

I —*Objects of the Fund.*

1 To provide, extend, equip, and maintain laboratories to be devoted to cancer research.

2. To encourage researches on the subject of cancer within the United Kingdom or in the British dominions beyond the seas.

3. To assist in the development of cancer research in various hospitals and institutions approved by the Executive Committee.

4 And generally to provide means for systematic investigation into the causes prevention, and treatment of cancer

Should the objects of the Fund be attained by the discovery of the cause and nature of cancer and of an effective method of treatment the Royal Colleges, with the consent of the Trustees, shall be empowered to utilise the fund (*a*) for equipping with the necessities for such treatment such hospital as they may select or (*b*) for forwarding research into other diseases.

II —*The President, Vice-Presidents, Trustees and Treasurer*

1. The future Presidents shall be appointed by the General Committee

2. The future Vice-Presidents shall be appointed by the General Committee.

3. There shall be five trustees of the Fund

4 Of the first trustees three may be nominated by the donors of sums of £1000 and upwards and one each by the Royal Colleges of Physicians and of Surgeons.

REBOUND

Q. LI L/1607

5 In the event of vacancies occurring by death, resignation, or other cause the General Committee may nominate new trustees and shall be called upon to do so in case the number shall fall below three

6 All moneys other than annual grants or subscriptions or sums specially given for definite objects or under special conditions, shall be invested as capital in the names of the trustees

7 The trustees shall pay over to the account of the Executive Committee all dividends on the invested trust funds as they fall due

8. If in any year the income derived from the invested capital is insufficient to defray the expenses authorised by the Executive Committee the trustees shall at the request of the Executive Committee realise sufficient funds to raise such sum as may be requisite to cover such deficiency

III —*General Committee*

1 The General Committee shall consist of: (*a*) The President (*b*) the Vice-Presidents (*c*) the five trustees, (*d*) the honorary treasurer (*e*) the Executive Committee (*f*) one member to be nominated by the Local Government Board, (*g*) one member to be nominated by the Colonial Office (*h*) one member to be nominated by the Royal Society (*i*) one member each nominated by the Royal College of Physicians of Edinburgh the Royal College of Surgeons of Edinburgh the Faculty of Physicians and Surgeons of Glasgow the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland (*j*) one member each nominated by the Royal Veterinary College London the Royal Veterinary College Edinburgh and the Royal Veterinary College of Ireland (*k*) donors of sums of £1000 and upwards whether given in one sum or more With power to add to their number

2 The General Committee shall nominate two members of the Executive Committee, who shall hold office for three years and shall be eligible for re-election

3 The General Committee shall meet at least once a year to receive reports from the Executive Committee on the general progress of the research an account of expenditure and the audited financial statement, and at such times as they may be summoned by the Executive Committee

4 The President shall summon a special meeting of the General Committee on receiving a requisition so to do, signed by five members of the General Committee

IV —*The Executive Committee*

1 The Executive Committee shall consist of —

(*a*) The President (for the time being) and two Fellows of the Royal College of Physicians of London to be nominated by the Fellows of such College	3
(*b*) The President (for the time being) and two Members of the Council of the Royal College of Surgeons of England to be nominated by the Council of such College.	3
(*c*) Two Members of the Laboratories Committee of the Royal Colleges of Physicians and Surgeons to be nominated by such Committee	2
(*d*) Two Members nominated by the General Committee	2
(*e*) One Member nominated by the Royal Society	1
(*f*) One Member nominated by the Royal Veterinary College London	1
	12

The members of the Executive Committee shall hold office for three years and shall be eligible for re-election

2. The Executive Committee shall have control of the income of the Fund which shall be expended in furthering the objects stated in Section I including the assignment of Funds: (*a*) for the erection or extension of laboratories or for the equipment of any existing laboratory in which investigations are or shall be pursued (*b*) for grants to individual workers in laboratories or elsewhere (*c*) for investigations other than those in laboratories (*d*) for the collection of statistical dietetic topographical and other information (*e*) for the salaries of any officials who may be appointed

3 The Executive Committee shall be charged with the general supervision and management of the arrangements to carry out the objects of the fund and particularly (*a*) they shall appoint the working and consultative staff under such conditions as they may think desirable (*b*) they may appoint a general superintendent of the investigations who may be director of the central laboratory and such assistants as may be considered necessary (*c*) they shall draw up the regulations under which the work of the staff shall be conducted in such rooms as may be placed at their disposal by the Royal Colleges or elsewhere (*d*) they may seek the advice of the members of the working and consultative staff on any questions relating to the objects of the fund and may appoint committees to conduct investigations or to collect statistics and information and may assign funds for the expenses of these investigations and for the remuneration of the members of these committees (*e*) they may appoint a secretary or other official to conduct the correspondence summon and attend the meetings keep the accounts write the minutes &c. (*f*) they may make arrangements for investigating methods of treatment in cases of cancer and malignant disease (*g*) they may make arrangements to establish a system of correspondence with foreign and colonial laboratories and workers (*h*) and generally they shall make such other arrangements as may seem to them best for the thorough investigation of this disease in all its aspects

4 The Executive Committee shall be required to report their proceedings from time to time to the General Committee

V —*Working and Consultative Staff.*

1 The working staff may consist of —(*a*) A general superintendent of the investigation who may be the director of the central laboratory (*b*) assistants to the general superintendent and director (*c*) any other persons who may be appointed to make special investigations

2. The consultative staff shall consist of persons skilled in scientific investigations representatives of various home and colonial Government departments physicians and surgeons attached to hospitals statistical experts and others appointed by the Executive Committee

3 The consultative staff may receive fees for attendance at meetings and may be remunerated for any services performed in connexion with the objects of the fund on such conditions as the Executive Committee may determine

A letter was read from Surgeon General A. F Bradshaw, C B, honorary secretary to the Oxford Eye Hospital, enclosing a copy of the decree and regulations of the University of Oxford establishing a readership in Ophthalmology and including the President of the Royal College of Surgeons of England as a member of the Electoral Board

---

METROPOLITAN HOSPITAL SUNDAY FUND

THE following are some of the principal amounts received at the Mansion House in aid of the Fund additional to those announced in THE LANCET of June 21st and June 28th The total now exceeds £43,000 There is now practically no chance of the Fund reaching the coveted £100,000, even with the generous offer of Mr George Herring to add 5s in the £ on all sums collected in churches The final total, it is expected, will be about £60,000

THE RECONSTITUTION OF THE BRITISH MEDICAL ASSOCIATION

THE members of the British Medical Association, at an extraordinary general meeting held at the Exeter Hall, Strand, London, on July 9th, decided by 82 votes to 43 to adopt the proposed new regulations for the Association.

Sir VICTOR HORSLEY, in proposing a motion to confirm the adoption of the rules pointed out that the merits and demerits of the new regulations had been discussed in the branches of the Association and in the committees formed for that purpose. There was also further consideration of the matter at Cheltenham. The present meeting was for the determination of the great general principles by which the Association was to be guided in the future. It was evident that the new rules would organise a machine of general political influence throughout the country Four years ago he had endeavoured to point out that this was the real purpose of the Association. Good scientific work was done by the Association already and it only remained for it to take its place as the leading organisation for the whole of the medical profession. The corporate bodies, the colleges and the universities had all their own objects to serve. But the British Medical Association was the only body that could take up the work By passing the new regulations there would be imposed on the Association the privilege of doing this work and at the same time securing to it the prestige which the work must bring to it. Recent events in connexion with the Government of this country in relation to the General Medical Council had not been so favourable as to make it safe for them as a profession to go on without having a combination of the kind proposed by the new regulations which would represent the views of the medical profession in the United Kingdom and elsewhere. Sir Victor Horsley continuing said that he had been a member of the General Medical Council for some years and he found that the Council was supposed to be a *quasi* sub-department of the Privy Council He was obliged to say supposed to be because during the last few months on several occasions the General Medical Council had been ignored by the Privy Council. As that was his experience of the inefficacy of the General Medical Council they would not be surprised when he said that he looked to the British Medical Association as the only body capable of bringing the General Medical Council into a more efficient condition. The Government was now beginning to realise that the Association was an important factor in the State The medical profession was paramountly a scientific one, always advancing and progressing and he contended that the new rules should receive the most sympathetic attention of all the members of the medical profession

Mr J S WHITAKER of Great Yarmouth in seconding the motion gave a history of the movement for the reform of the Association.

Dr J G GLOVER, who was the next speaker said that the meeting was engaged in discussing momentous issues. He asked what the argument was for the enormous change proposed. It was said that the reform was necessary because the profession was at the present moment weak and impotent and Parliament took no notice of its views. This Dr Glover denied entirely He thought the language was exaggerated and extremely inaccurate. Parliament in passing the Midwives Bill had accepted an entirely new principle in medical legislation as put forward by the medical profession represented by the British Medical Association and the General Medical Council Where was there any impotence, he asked in beating the Government, the Home Secretary in the House of Commons and the Lord Chancellor in the House of Lords? Dr Glover then went on to show that the action of the General Medical Council in connexion with certain friendly societies disproved the charge of the Council being powerless. He considered that the new rules were fantastic, new fangled, costly and altogether degrading In regard to the proposed delegates he said that their position would be a degrading one. The new rules would add immensely to the complications of the Association and would impose another set of masters upon the executive.

Dr DOUGLAS also addressed the meeting and he was followed by Dr J BRASSEY BRIERLEY Mr STAMFORD FELCE, Dr O SULLIVAN and Mr H. NELSON HARDY

On a show of hands the voting was declared to be 82 in favour of the new regulations and 43 against.

ASYLUM REPORTS

Salop and Montgomery County Asylum (Annual Report for 1901) —The average number of patients resident during the year was 800 comprising 361 males and 439 females The admissions during the year amounted to 191—viz. 99 males and 92 females Of these 146 were first admissions Mr Alan Rigden, the acting medical superintendent, states in his report that in addition to the patients resident in the asylum there were 25 male patients boarded out at Forden workhouse. Dr Arthur Strange the medical superintendent, died on May 11th, 1902, after a tenure of office of over 30 years, at the asylum and his successor has not yet been appointed. The number of cases discharged as recovered during the year amounted to 79—viz. 36 males and 43 females, or 98·8 per cent. of the average number resident. The deaths during the year amounted to 82—viz. 41 males and 41 females or 10·25 per cent, as calculated on the same basis. Of the deaths three were due to renal disease, four each to epilepsy and colitis, five to general paralysis of the insane, six to cardiac disease, seven to apoplexy 14 to pulmonary phthisis, 16 to senile decay and the rest to other causes. Until the early part of the year the health of the asylum was reasonably good, but in February 1902, an outbreak of influenza occurred, beginning in the female department and subsequently attacking the men Up to May 17th, 1902, 31 patients have died of this disease out of a total of 78 attacked making a death rate of 39 74 per cent." An outbreak of swine fever occurred on the farm necessitating the slaughter of nearly all the pigs and leading to a considerable reduction of the profit on the farm account. The average weekly cost of maintenance has been 8*s* 11*d* per patient. The committee of visitors states in its report that owing to the increase in the cost of maintenance it has been found necessary to raise the weekly charge to the unions from 8*s* 6*d* to *9s 6d per patient as from July 1st, 1902.* The sum of £1033 13*s* 6*d* has been expended during the year in additions, alterations and improvements including £757 8*s* 3*d* for the construction of the sewer connecting the asylum with the borough of Shrewsbury system. The committee has at present under consideration the question of electric lighting for the asylum The report of the Commissioners in Lunacy is not included in the present annual report

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9260 births and 4384 deaths were registered during the week ending July 5th. The annual rate of mortality in these towns, which had been 15 0 14 9 and 15 1 per 1000 in the three preceding weeks, further increased last week to 15 4 per 1000. In London the death rate was 15 1 per 1000 while it averaged 15 5 in the 75 other large towns. The lowest death rates in these towns were 7 6 in Hornsey 7 8 in Reading 8 0 in Derby 8 6 in Willesden 9 2 in Smethwick and in Leicester and 9 3 in Swansea the highest rates were 19 7 in Sunderland 20·0 in Tynemouth 20·3 in Liverpool 20 8 in Gateshead, 22 5 in Hanley 22 9 in Wigan, 25 5 in St. Helens and 25 7 in Middlesbrough. The 4384 deaths in these towns last week included 522 which were referred to the principal infectious diseases, against 496, 481 and 476 in the three preceding weeks of these 522 deaths 125 resulted from whooping cough, 117 from measles, 83 from diarrhœa, 64 from scarlet fever 64 from diphtheria, 53 from fever" (principally enteric) and 16 from small pox. No death from any of these diseases was registered last week in Hastings Northampton Great Yarmouth Smethwick Bootle, or Rotherham while they caused the highest death rates in Leyton, Hanley West Bromwich St. Helens, Barrow in Furness, South Shields Gateshead, and Rhondda. The greatest proportional mortality from measles occurred in Plymouth Devonport, Burton-on Trent, West Bromwich Bury Barrow in Furness Gateshead and Rhondda from scarlet fever in West Bromwich, Birmingham, and St. Helens, from diphtheria in Hanley Oldham, Cardiff, and Rhondda from whooping-cough in Aston Manor Wigan Salford Tynemouth, and South Shields from fever in Leyton and

Birkenhead, and from diarrhœa in Warrington, Stockton on-Tees, and West Hartlepool Of the deaths from small pox registered last week 13 were of persons belonged to London, one to Tottenham, one to Walthamstow, and one to Swansea. The Metropolitan Asylums hospitals contained 677 small-pox patients at the end of last week, against numbers decreasing from 1515 to 837 at the end of the 10 preceding weeks, 58 new cases were admitted during the week, against 157, 107, and 129 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital which had increased from 2207 to 2496 on the seven preceding Saturdays, had declined again to 2432 on Saturday last, July 5th, 256 new cases were admitted during the week, against 282, 378, and 276 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 166, 173, and 194 in the three preceding weeks, declined again to 168 last week, and were four below the corrected average. The causes of 54, or 1 3 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Nottingham, Salford, Bradford, Leeds, Newcastle, and in 45 other smaller towns, the largest proportions of uncertified deaths were registered in Northampton, Leicester, Liverpool, Rochdale, and Sunderland

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 16 4 and 19 2 per 1000 in the two preceding weeks, declined again to 16 3 per 1000 during the week ending July 5th, but showed an excess of 0 9 per 1000 over the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 7 8 in Perth and 10 9 in Aberdeen to 17 9 in Paisley and 18 0 in Dundee The 528 deaths in these towns included 24 from diarrhœa, 16 from whooping cough, 13 from measles, five from scarlet fever, five from diphtheria, and three from "fever" In all 66 deaths resulted from these principal infectious diseases last week, against 54 and 57 in the two preceding weeks These 66 deaths were equal to an annual rate of 2 0 per 1000, which was 0 2 per 1000 above the mean rate last week from the same diseases in the 76 large English towns The fatal cases of diarrhœa, which had been 18, 17, and 16 in the three preceding weeks, rose again last week to 24, of which 13 occurred in Glasgow, four in Dundee, two in Edinburgh, two in Aberdeen, and two in Leith The deaths from whooping-cough, which had been 13 and 14 in the two preceding weeks, further increased to 16 last week, and included 10 in Glasgow, two in Edinburgh, and two in Dundee The fatal cases of measles, which had declined from 22 to 15 in the four preceding weeks, further decreased last week to 13, of which six were registered in Edinburgh, three in Glasgow, and three in Paisley The deaths from scarlet fever, which had been four in each of the two preceding weeks, increased to five last week, and included four in Glasgow The fatal cases of diphtheria, which had been two and four in the two preceding weeks, further rose last week to five, of which two were registered in Glasgow and two in Edinburgh. The three deaths from "fever" showed a slight decline from the number in the preceding week, and included two in Paisley The deaths referred to diseases of the respiratory organs in these towns, which had been 96 and 101 in the two preceding weeks, declined again to 87 last week and were eight below the number in the corresponding period of last year The causes of 24, or nearly 5 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 17 9 and 19 9 per 1000 in the two preceding weeks, declined again to 18 9 per 1000 during the week ending July 5th During the past four weeks the death-rate has averaged 19 1 per 1000, the rates during the same period being 14 5 in London and 17 4 in Edinburgh The 139 deaths of persons belonging to Dublin registered during the week under notice were six below the number in the preceding week, and included 11 which were referred to the principal infectious diseases, against 10, eight, and nine in the three preceding weeks, of these, six resulted from measles, two from "fever," two from diarrhœa, one from scarlet fever, and not one from either small-pox, diphtheria, or whooping cough These 11 deaths were equal to an annual rate of 1 5 per 1000, the death rates from these principal infectious diseases during the same period being 1 8 in London and 2 1 in Edinburgh. The fatal cases of measles, which had been four, five, and three in the three preceding weeks, increased again last week to six, while the two deaths from "fever" showed a decline of two from the number in the preceding week The 139 deaths in Dublin last week included 20 of children under one year of age and 35 of persons aged upwards of 60 years, the deaths of infants showed a decline, while those of elderly persons slightly exceeded the number in the preceding week Eight inquest cases and seven deaths from violence were registered, and 53, or considerably more than a third, of the deaths occurred in public institutions The causes of 10, or more than 7 per cent, of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING JUNE, 1902.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the cities and boroughs in the county of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 10 0 per 1000 of the population, estimated at 4,579,107 persons in the middle of the year In the three preceding months the rates had been 11 9, 10 5, and 10 3 per 1000 respectively The rates were considerably below the average in Paddington, Kensington, Hammersmith, Hampstead, Battersea, and Woolwich, while they showed the largest excess in St. Pancras, City of London, Bethnal Green, Stepney, Poplar, and Southwark. The prevalence of small pox, which had been declining in the two preceding months, showed a further diminution last month, among the various metropolitan boroughs this disease was proportionally most prevalent in Hackney, Holborn, Shoreditch, Bethnal Green Stepney, Poplar, and Southwark. The Metropolitan Asylums hospitals contained 837 small-pox patients at the end of June, against 1526, 1442, and 1274 at the end of the three preceding months, the weekly admissions averaged 145, against 461, 319, and 260 in the three preceding months. The prevalence of scarlet fever during the month under notice showed a slight excess over that recorded in the preceding month, the greatest proportional prevalence of this disease occurred in St Pancras, Stoke Newington, Bethnal Green, Southwark, Camberwell, and Lewisham The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had been 2113, 2176, and 2222 at the end of the three preceding months, had further risen to 2439 at the end of last month, the weekly admissions averaged 251, against 258, 258, and 274 in the three preceding months The prevalence of diphtheria during June showed no variation from that recorded during the preceding month, among the various metropolitan boroughs this disease was proportionally most prevalent in Fulham, Stepney, Poplar, Southwark, Bermondsey, Camberwell, and Lewisham. There were 975 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 1123, 1035, and 960 at the end of the three preceding months, the weekly admissions averaged 152, against 156, 140, and 146 in the three preceding months The prevalence of enteric fever last month showed a considerable excess over that recorded in the preceding month, the greatest proportional prevalence of this disease occurred in Chelsea, St Marylebone Stoke Newington, Finsbury, Bethnal Green, Poplar, and Greeenwich The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 121, 115, and 127 at the end of the three preceding months, had further increased to 195 at the end of June, the weekly admissions averaged 38, against 17, 17, and 19 in the three preceding months Erysipelas was proportionally most prevalent in St Marylebone, Holborn, Finsbury, Shoreditch, Southwark, and Deptford. The 15 cases of puerperal fever notified during the month included three in Kensington and two each in Islington, Bethnal Green, Wandsworth, and Lewisham.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JUNE 1902.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1902.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES											Deaths from all causes.	Death rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever	Diphtheria.*	Typhus fever	Enteric fever	Other continued fevers.	Puerperal fever	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living	Small pox.	Measles.	Scarlet fever	Diphtheria.*	Whooping cough.	Typhus fever	Enteric fever	Other continued fevers.	Diarrhoea.	Total	Annual rate per 1000 persons living

* Including membranous croup.

boroughs, the deaths occurring in public institutions having been distributed among the various boroughs in which the deceased persons had previously resided. During the four weeks ending June 28th the deaths of 4898 persons belonging to London were registered, equal to an annual rate of 13 9 per 1000, against 20 4, 16 8, and 15 9 per 1000 in the three preceding months The lowest death rates last month in the various metropolitan boroughs were 6 7 in Hampstead, 10 1 in Lewisham, 10 2 in Greenwich, 11 0 in Hammersmith, 11 7 in Woolwich, and 11 9 in Stoke Newington, while the highest rates were 17 0 in Stepney, 17 1 in Holborn and in Bermondsey, 17 3 in Bethnal Green, 19 3 in Finsbury, and 19 9 in Southwark The 4898 deaths from all causes included 99 from small pox, 198 from measles, 43 from scarlet fever, 53 from diphtheria, 151 from whooping cough, 29 from enteric fever, and 57 from diarrhœa, in all, 630 deaths resulted from these principal infectious diseases. No death from any of these diseases was recorded last month in Hampstead, in the other metropolitan boroughs they caused the lowest death rates in Paddington, Westminster, Stoke Newington, Greenwich, and Lewisham, and the highest rates in Chelsea, St. Pancras, Finsbury Stepney, Southwark, and Bermondsey The 99 fatal cases of small pox were 55 below the number in the preceding month, the greatest proportional mortality from this disease occurred in St. Pancras, Stoke Newington Poplar, Southwark, Bermondsey, and Camberwell The 198 deaths from measles were 87 below the corrected average number, among the various metropolitan boroughs this disease was proportionally most fatal in Chelsea, Hackney, Finsbury, Southwark, Battersea, and Wandsworth. The 43 deaths from scarlet fever showed a decline of 24 from the average number in the corresponding periods of the 10 preceding years, the greatest proportional mortality from this disease was recorded in Paddington Westminster, Finsbury, Lambeth, and Deptford. The 53 fatal cases of diphtheria were 91 below the corrected average number, among the various metropolitan boroughs this disease was proportionally most fatal in St. Marylebone, St Pancras, Holborn the City of London, Poplar, and Lewisham. The 151 deaths from whooping cough were within one of the average number in the corresponding periods of the 10 preceding years, the greatest proportional mortality from this disease occurred in St. Pancras Finsbury, Shoreditch, Bethnal Green, Southwark, and Camberwell The 29 deaths from enteric fever were slightly below the corrected average number, among the various metropolitan boroughs this disease was proportionally most fatal in Kensington, Shoreditch, Southwark, Battersea, and Camberwell. The 57 fatal cases of diarrhœa were more than 100 below the decennial average for June, the highest death rates from this disease were recorded in Kensington, Hammersmith, Fulham, Chelsea, and Bethnal Green, In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was more than 25 per cent. below the average.

Infant mortality in London during June, measured by the proportion of deaths of children under one year of age to registered births, was equal to 112 per 1000 The lowest rates of infant mortality were recorded in Westminster, Hampstead, St. Marylebone, Lambeth, Greenwich, and Lewisham, and the highest rates in Paddington, Chelsea, Finsbury, City of London, Bethnal Green, Southwark, and Wandsworth.

THE SERVICES

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel J Battersby is appointed to the medical charge of the Station Hospital, Quetta. Lieutenant L J S Cahill has been transferred from the Bombay District to the Poona District. Surgeon Major C L Fraser, A.M R, assumes temporary medical charge of troops, Station Hospital, &c., Berwick on Tweed, vice Lieutenant-Colonel J Stevenson, A.M S, retired pay, who assumes medical charge of troops, Station Hospital, &c., Aberdeen, vice Surgeon Lieutenant-Colonel W S Cheyne, A.M R.

THE ARMY AND TYPHOID FEVER.

Notwithstanding that the war in South Africa is now over we trust that the question as to whether something cannot be done in the direction of lessening or abolishing the deplorable prevalence of enteric fever in armies in the field will not be lost sight of and that the consideration of such an important and pressing matter will not be relegated to some future time, but that it will be undertaken at once No time can be more opportune than the present while the facts connected with the late campaign are still fresh in everybody's mind and now that the advent of peace has removed or lessened the stress and strain more or less inseparable from war If we turn to the medical history of military campaigns we are confronted with the presence of typhoid fever as one of the gravest contributory causes of mortality, sickness, and inefficiency among the belligerents We need scarcely say that this was so in respect of the British forces in South Africa, for enteric fever was almost throughout the whole course of the late war the most prominent feature in the casualty returns. Nor is it only at such times that enteric fever has proved to be a scourge to the army, for this disease constitutes a terrible annual drain on the life and health of our young soldiers in India We are above all things, then, anxious to see this matter taken up in an earnest and practical spirit with a view to ascertain whether anything can be done Dr H. E Leigh Canney has, as our readers are well aware, put forward a scheme by which he claims, among other things that the amount of this and other ' water borne" army diseases might be greatly lessened, the medical work of the army much reduced, and a great saving in the way of money and transport effected. The basis of his scheme is to safeguard the army against infection through the most common (though not the exclusive) source of it among troops serving in the field by providing them with a "safe" water supply and by pointing out at the same time a method by which this might practically be accomplished About a year has elapsed since Dr Leigh Canney first definitely put forward his proposals in this respect and we recommended that instead of being merely theoretically discussed they should be practically tried It may be mentioned that, with a similar object in view, in the United States army a water sterilising apparatus, known as the Waterhouse Forbes apparatus, is used. Dr Leigh Canney has, it is well known, continued to pursue his labours in the meantime and to press the subject upon public attention He is naturally surprised at the delay which has occurred and still more dissatisfied with the way in which it is now apparently proposed to give effect to a practical trial of his scheme He has consequently felt compelled to call attention to the conditions under which this should be undertaken, and in a long and forcible letter written in an enthusiastic spirit, which appeared in the *Times* of June 28th, he has fully set forth the past history and present state of the question In this communication, which should be read *in extenso*, he, it will be seen, lays down eight essential details as the conditions which he considers are required to be fulfilled to secure the success of his scheme It is not that he would have merely a trained "water section" provided as a permanent institution in the army and furnished with the necessary material and properly qualified agents for doing the work, but he would also make the *non medical officers* of the army responsible for executive sanitary work and for the incidence of water borne diseases in their several and respective units We have so frequently adverted in the past to the subjects of army sanitation in the field and to the possible organisation of an executive sanitary corps acting under the authority and direction of expert sanitary officers that there is no need to enter upon them now While we do not by any means seek to close our eyes to the difficulties in the way of preventing the occurrence and spread of typhoid fever under the conditions of war we are nevertheless of opinion that this question of the provision of a "safe" water supply for the troops engaged, and, indeed, the whole subject of field army hygiene, require to be considered thoroughly and to be threshed out by the Army Medical Advisory Board or by some committee specially appointed for the purpose.

HEALTH OF THE ARMY

The Army Medical Department Report for 1900, which has just been issued as a blue book, states that the average strength of European troops serving at home and abroad (exclusive of South Africa) in 1900 was 226,276 officers, non commissioned officers, and men The total number of admissions to hospital was 187 284 and the total deaths were 2242. The admissions represent a ratio of 827 7 per 1000 of strength, the deaths one of 9·05 per

1000 on a strength of 247 819 Amongst the troops serving in the United Kingdom the admission and constantly-sick rates were lower and the mortality rate was higher than in 1899 At Gibraltar the admission and constantly sick rates were lower but the death rate was somewhat higher than in 1899 At Malta, including Crete, the admission rate was higher and the death and constantly sick rates were lower than in the previous year In Canada there was an increase in the admission, mortality and constantly sick rates. At Bermuda enteric fever again showed a decline At Barbados and at Jamaica the health of the troops was very good. In Western Africa malarial fevers furnished the chief cause of admissions to hospital. In Mauritius the general health of the troops was much better than usual and in Ceylon there was a marked decrease in the admissions for malarial fevers In the Straits Settlements the health of the troops has been exceptionally good. In China the ratios of admission and constantly sick were lower than in 1899 In India there was a decline in the admission and constantly sick rates but an increase in the death and invaliding rates. In Egypt the general health of the troops was good and bore a satisfactory comparison with the previous year

An Army order has been issued which states that all present members of the Nursing Service and members of the Army Nursing Reserve who have been in military employment during the war in South Africa shall be eligible for appointment in Queen Alexandra s Imperial Military Nursing Service if recommended by the Nursing Board

THE KING'S DINNER TO THE POOR

Some 40 volunteer medical officers and 28 squads of fully equipped stretcher squads were distributed among the places at which the guests invited to the King s dinner to the poor were assembled on July 5th. The services of medical practitioners, men of the St. John Ambulance Brigade, and hospital nurses were also requisitioned In the evening a number of volunteer medical officers dined together after doing duty at the King s dinner at the Cecil Hotel, ' to drink the King s health," which was heartily done, and a telegram of congratulation on the progress of His Majesty s illness was sent to Buckingham Palace. The following reply was received Buckingham Palace —To Surgeon Major Marshall, Chairman of Volunteer Medical Officers' Dinner Hotel Cecil Strand —Your telegram conveying the kind congratulations on the King s progress towards recovery of the volunteer medical officers dining together under your presidency at the Hotel Cecil last night shall be submitted to His Majesty at an early opportunity —DIGHTON PROBYN " Surgeon Major John J de Z Marshall honorary secretary of the Volunteer Medical Association wishes us to state that he will be glad to do his best to obtain Coronation mugs and the King s Hearty Invitation Cards for medical officers and men who were unable to obtain them at the dinner by applying through the Lord Mayor on receiving lists authenticated by medical officers of health.

CHIROPODISTS FOR THE ARMY

The War Office of this country is following the example adopted in the armies of other countries in view of securing and developing the marching capacity of the soldier During the big American war chiropodists to the army were appointed by the United States Government and in the German army the greatest attention is paid to the soldier s feet An Army Order has just been issued by the War Office providing that a soldier not above the rank of sergeant may be employed as a chiropodist in each infantry battalion provided he has undergone a short course of instruction and has obtained a certificate of proficiency in chiropody Battalion chiropodists are to receive sixpence a day in addition to their daily pay While we regard this as a good practical measure and as conferring a boon upon the soldier care will obviously have to be taken that only those who have been properly instructed are allowed to exercise their skill in this respect.

MEDICAL EXAMINATION OF CANDIDATES FOR THE ARMY

The medical attendants of parents who contemplate educating their sons for the army frequently seek information from us as to the effect which some minor ailments of youth may have upon candidates when being examined by the Army Medical Board previously to receiving a commission. With regard to the removal of tonsils we understand that, other things being equal, the operation would not affect the candidate prejudicially He must be up to a certain standard of height and chest girth and be free from organic disease. His vision without glasses must be up to a fixed standard and if there is an error of refraction it must be capable of correction to another fixed standard It should be generally known that parents have now the right to have boys examined by a medical board before allowing them to join army classes.

NAVAL MEDICAL SUPPLEMENTAL FUND

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund held on July 8th, Sir J N Dick K.C B being in the chair the sum of £40 was distributed among the several applicants.

Correspondence.

'Audi alteram partem '

PERITYPHLITIS

To the Editors of THE LANCET

SIRS,—Many will have read with much interest the letter in THE LANCET[1] of my revered teacher Sir Samuel Wilks, asking When will surgeons cease to proclaim to the world their ignorance of the existence of the above-named disease until operative means were first used for its cure? and also the letter of my friend Dr P H Pye-Smith in the *British Medical Journal* of July 5th with its quiet cynicism at the supposed benighted ignorance of surgeons. But I rather imagine that neither of these distinguished physicians *sincerely* believes in the imputed unenlightenment which has aroused the indignation of the one and the scarcely veiled ridicule of the other Their love for their old school and the cherished memories of their early training and teaching have doubtless led them to repudiate even the semblance of a claim for modernness ' for a disease which has received practical recognition for the greater part of a century

My own first recollection of disease due to the appendix goes back to a time long prior to my clerkship to Dr Barlow and Dr Rees and my dressership to Cooper Forster and Hilton—to the year 1854 or 1855 in fact, when as a schoolboy I heard of the sudden death of a young lady the only daughter of patients and friends of my father and an occasional playmate of my sisters. We were told that her illness was inflammation of the membrane covering of the bowel She died from an alarmingly acute attack which extended over one or two days only My father made the post-mortem examination and found that a body like a cherry stone had ulcerated through the appendix and had caused the fatal trouble. This case created great dismay in our young minds and used often to be spoken of by all of us at home—not to be sure, as one of 'appendicitis or perityphlitis but in remembrance of our lost comrade and because of the terrible dangers supposed to arise from the proverbial cherry-stone " Later after I had studied in the wards of Guy's Hospital, the same case was several times referred to in conversations with my father a country practitioner as a type of a group of cases of acute peritonitis. I also recall the fact that one of the earliest cases of iliac phlegmon' under my charge—an enormous abscess containing horribly foul pus—was seen with me by the late Mr Hulke about the year 1871, and was considered to be connected with the cæcum and its appendix Many of my contemporaries must have had as early or possibly earlier similar experience.

The author of the address criticised by Sir Samuel Wilks and Dr P H. Pye-Smith both in the headline (The Appearing of Appendicitis) of his opening section as well as in the first three paragraphs of this section does certainly seem to imply that appendicitis is a modern disease and speaks of its almost abrupt appearance" as one of the most remarkable circumstances in the history of medicine in the closing years of the nineteenth century " But in subsequent paragraphs Sir Frederick Treves acknowledges that this clumsily named malady is not a new disease " and he adds *nor is there evidence to support the suggestion that it has* undergone any recent and remarkable recrudescence or that it has become more frequent in its appearance " He alludes, it is true, to the "long-ignored appendix," and to appendicitis as having "no coherent existence 20 years ago", still he tells us that the disease "can be traced back to distant centuries" and he thinks that the cave man occasionally succumbed to its ill-effects. Further, he admits the existence of many published isolated cases and refers to the monograph of Burne (1837) and the articles by Mélier (1827) on the "appendix as a cause of certain inflammatory troubles in the right iliac region." Thus, whilst seeming to declare the disease as one of modern date, Sir F. Treves acknowledges quite as fully as his critics that it is as old as the hills and was long ago described by many writers.

---

[1] THE LANCET July 5th 1902, p 44

Another point raised in this interesting address appears to be claimed as a discovery within the same short and recent period. Sir F. Treves writes: "The rapidity with which the peritoneum can isolate inflammatory effusion and render pus encysted was not understood and consequently localised iliac abscesses were supposed to occupy the connective tissue of the iliac fossa." But the critic might fairly ask (besides other questions), What about encysted traumatic dropsy of the abdomen? Let the reader refer, if he will, to a work published in 1878 (Agnew's Surgery, vol. i., p. 392). Agnew there states, "The circumscribing walls of these cysts are the result of a chronic peritonitis." After pointing out that these cysts may be formed in various ways between the omentum and the intestinal peritoneum, Agnew goes on to say that they "may be converted into purulent sacs," and gives as illustrations a case in which two gallons of purulent fluid were drawn from such a cyst between the omentum and the intestines, and another in which he drew off over three gallons from a cyst on the right side of a woman's abdomen. After describing the symptoms and treatment of encysted dropsy of the peritoneum Agnew ends by saying, "When the cysts suppurate it will be best to open them, evacuate the contents, and treat by drainage tubes and carbolic water." Here there is a full recognition of the limiting of fluids by adhesive peritonitis, and a treatment is recommended which very closely resembles that employed in 1902 for an abscess connected with the appendix.

I may be permitted, perhaps, to remark that all surgeons will probably not agree with the statement that the clinical phenomena which are familiar under the name of "an attack of appendicitis" are due to peritonitis in the region of that organ, that some will consider Sir F. Treves is unnecessarily hostile in his remarks against "the classification of appendicitis," but they will welcome his distinct recognition of "ultra acute" and other clinical varieties of the disease, though he does not designate them by names such as "fulminating," "suppurative," and 'relapsing." Moreover, it is known that all surgeons do not endorse his opinions as to the advisability of non interference during an acute attack.

Surgeons of experience who only remove the appendix during the quiescent period may look to a mortality of only a fraction per cent., whilst those who do not limit their operations to this period may not surpass, even if they equal, Dr. Mynter's results of 81 recoveries and 34 deaths in 115 cases operated upon by him *at some period during an acute attack*. We want figures to tell us how many patients die during an acute attack unoperated upon, and how many die or recover only after a protracted illness when operated upon after the disease has passed into an advanced stage of suppuration. It would be good to learn, also, how many patients who otherwise would have died have their lives saved or are spared long periods of convalescence from suppuration by the practice of operating in acute attacks as soon as the diagnosis is made. There must be many surgeons who with melancholy feelings have had occasion to ask themselves, "Had this patient been operated upon two days, or even one day earlier, might not his life have been saved?" and who in other cases with happier thoughts have reflected, "Had the operation been postponed another 24, or even 12, hours this patient must have died."

It is to be hoped that the concluding paragraph of Dr. P. H. Pye Smith's letter, and the passages in Sir Frederick Treves's address to which it makes reference, will not be too freely "read into" clinical practice, and thus act to deter from operating in cases in which an operation alone will enable the sufferers to enjoy long life and lead laborious days. But, Sirs, I will not pursue this theme, for my object in writing at all on the subject is merely to suggest with as much modesty and diffidence as I possess that surgeons are probably not quite so ignorant as these greatly-respected and highly-esteemed physicians would lead your readers to suppose.

I am, Sirs, yours faithfully,

Cavendish-square, W., July 7th, 1902. HENRY MORRIS.

To the Editors of THE LANCET

SIRS,—Personal experience of a disease impresses its features strongly on the mind. My own experience of perityphlitis may be of interest, especially in connexion with the observations of Sir Samuel Wilks. Between 26 and 34 I had five or six definite attacks, the last of great severity. In none was there any spot of greater tenderness to suggest that the affection started from the appendix. My personal observation generated a strong conviction of the origin of the form from which I suffered. In his teaching Sir William Jenner used to insist on the variation in the amount of peritoneum over the cæcum in connexion with intussusception, which he held to occur chiefly when the covering is so complete as to give rise to a meso-cæcum and consequent mobility. It seemed to me that true perityphlitis occurs especially when the cæcum is imperfectly surrounded by peritoneum, so that part of the intestinal coat is in direct relation to the extra peritoneal connective tissue, and that, in this, cellulitis is excited by the spread of inflammation from the mucous membrane of the bowel. Certainly every attack I had was distinctly set up by intestinal catarrh. Besides the definite attacks with some induration, the cæcum seemed to become prone to be slightly inflamed, for I had many slight attacks in which the cæcum became distended and very tender, the state passed with a day's rest, hot fomentations, and the avoidance of any action of the bowels.

The last attack was very instructive. Beginning in the usual way, the cellulitis which, I assume, was excited from the mucous membrane, spread, clearly in the extra peritoneal tissue, and the induration that resulted extended as far as the middle line of the abdomen. I suppose that there was no indication of suppuration, for Sir William Jenner, who kindly looked after me, did not think a surgeon's opinion necessary. In the course of a few weeks the whole gradually disappeared, in spite of an incidental attack of catarrhal jaundice. It was before the days of "appendicitis." I wonder whether, with such extensive induration, I should have escaped operation and the removal of the appendix at the present day. I do not think my prospects of recovery would have been increased thereby. I should add that no one recognised more clearly than Sir William Jenner the fact that dangerous local inflammation is often excited by the impaction of substances in the appendix.

I have met with several illustrations of one other fact which my experience illustrated—that a very severe attack of perityphlitis, whether operated on or not, is usually the last. I think the explanation is that the connective tissue is left in an altered, cicatricial condition which becomes less and less prone to inflammation as the cicatricial change is more and more complete.

I am, Sirs, yours faithfully,

July 7th, 1902. W. R. GOWERS.

To the Editors of THE LANCET

SIRS,—It may possibly interest some of your readers at this moment to know that in 1884, Sept. 20th, I published in the now extinct *Medical Times and Gazette* a fatal case of well-marked perityphlitis (as it was then called), as part of a series of summer clinical lectures on peritonitis in its various forms which occupied the two last years of the journal in question. This was just two years before the appearance of the admirable research of Dr. Fitz to which Sir Frederick Treves attributes not only the name appendicitis, but all the more modern aspects of the disease resulting from that name. It may, therefore, be worth while to remark that although my lecture (being strictly clinical and not systematic) made no attempt at a large display of authorities, it may fairly be taken as representative of the knowledge by physicians of the diseases included under the names typhlitis and perityphlitis at that date, when surgery had not as yet (except in very peculiar circumstances) put in a special claim to the management of such diseases. The first point that appears to require notice in view of more recent researches is that the case in 1884 was absolutely the first case that I could find in my own records of a fatal result in perityphlitis during the 10 years in which the Western Infirmary had been open. A careful inspection of the records of the pathological department discovered two more such cases as well as two others which had been sent in from without for examination. On the whole, and speaking with such diffidence as is necessary to allow for lapses of memory I am inclined to think that this was the very first fatal case that had occurred to myself personally either in hospital or consulting practice, and this would accord very well with the conclusion of Sir Frederick Treves, who places the mortality of the disease without operation as no higher than 5 per cent. I am willing to admit, however that the whole circumstances of this fatal case as viewed in the light of later experience incline me to the opinion that an operation ought to have been performed although owing to the subsidence of the temperature and all the acute symptoms we were led into a practice of expectancy Four years later I had the pleasure, along with the late Sir George MacLeod of saving by operation from imminent peril a professional brother whose case in every detail seems to correspond exactly with that of our King and who is now performing the duties of a large practice without any trace of a subsequent recurrence of symptoms. But in view of the letter by Sir Samuel Wilks which appeared in your columns last week it seems important that I should call attention in your columns to the fact that not only was the share of the appendix in the morbid process not ignored, but it was most carefully treated as the result of experience in the Western Infirmary as well as of previous research elsewhere, the whole subject being discussed with reference to a paper by the late Dr Hilton Fagge in *Guy's Hospital Reports* for 1875. I am sorry my attention was not drawn to Dr Addison s much earlier statements which are only one more proof of the genius and penetrating sagacity of that great physician but I think that the perusal of this lecture in detail and in its whole surroundings will satisfy anyone that in 1884 at least the share of appendix disease in perityphlitis was by no means overlooked, and that the reparative processes incidental to a limited peritonitis in such circumstances were most carefully insisted on.

I am Sirs, yours faithfully

Edinburgh July 7th 1902. W T GAIRDNER.

THE BETTERMENT OF LONDON

To the Editors of THE LANCET

SIRS,—I ask permission to place before the public, through the medium of your influential journal some particulars regarding the recently established Betterment of London Association of which I have accepted the presidency for the current year The press has always been foremost in the advocacy of any movement which has the public welfare at heart and I therefore feel confident of its support in the present instance. The principal items of our programme are as follows.

Section I—To agitate for a quieter London primarily in respect to unnecessary and objectionable street noises such as those produced by organ grinders, costermongers, and newsboys for a healthier and cleaner London obtainable by a constant removal of refuse of all descriptions and in other ways, and for a more clearly designated London. In this latter respect the association will direct attention, amongst other matters, to the illegible naming of public thoroughfares and to the insufficient manner in which names are illuminated after dusk.

Section II—To agitate against the immigration of pauper aliens (obtaining legislation thereon if necessary) against the employment—in the street—of children under 10 years of age and after 9 o clock P M of children under 12 years of age. To draw attention to the extreme danger to health engendered by the obnoxious habit of expectorating in public conveyances and buildings to promote action against the sale of impure ice cream (another very fruitful source of disease) to direct the attention of the authorities to the Act relating to betting and gambling in public places, and to agitate against the constant digging up of the highways to the great inconvenience of the community

Section III—To impress upon the municipal and other authorities of the metropolis the necessity of enforcing as in Liverpool the registration of street musicians" and street traders, including newspaper vendors and to impress upon the railway companies the desirability of freeing their stations and approaches from all idlers and hawkers

From these statements it will be seen that the association is instituted for the service of the public and that it has at heart the desire to make London—what it certainly is not at present—the best governed city in the world. The propaganda will be carried on by public meetings and conferences by deputations and petitions to local authorities to the office of works, &c., by the publication of health leaflets of literature relating to Acts of Parliament, by laws, &c, and in various other ways.

In conclusion, I would add that if any of your readers are disposed to coöperate in this much needed movement for the betterment of London, and thus help it to grapple with many nuisances which ought to be abolished, they should communicate with the honorary secretary Mr Bowden Green, at the offices of the association, 1, Finsbury circus E C.

I am Sirs, yours faithfully

July 5th, 1902. W B. RICHMOND President.

OBSERVATIONS ON DIET

To the Editors of THE LANCET

SIRS,—Dr F W Forbes Ross dissents from my view that the diet of old people should be spare. He has no sympathy with arguments metabolical", he thinks they savour rather of the diabolical' and that 'an ounce of practice is worth a ton of theory" If by this he desires to protest against the all too-prevalent tendency to base treatment on theoretical considerations rather than upon experience I am with him. Medical treatment must ever be to a large extent empirical Nevertheless *a priori* reasoning may give trustworthy indications and the physiological arguments in favour of the aged living on a spare diet seem to me to be unmistakeable mere common sense in fact. They are, briefly as follows. In old age the active cells, such as the epithelial, atrophy while there is overgrowth of the comparatively inert fibrous tissues and *pari passu* with these retrograde changes there is a general depression in the sphere of vital activity the vital fire no longer blazes as in the period of lusty youth and prime, but rather smoulders or feebly flickers. Hence the furnace as represented by the tissues requires less fuel in the shape of food than in the earlier years and not only so but the atrophied digestive glands are less capable of coping with food and the excretory glands less able to rid the system of the waste products to which it gives rise. Have I thus far pursued my argument on the rock of common sense, or have I been treading the quicksands of mere fanciful theory?

So much for *a priori* argument But after all as Dr Ross observes questions of this sort must ultimately be decided by practice. Well, my experience is all in favour of the thesis I put forward. I find that the healthiest, and therefore the happiest, and longest-lived old people are spare eaters.

Let us see what the Doctor commits himself to He administers to aged broken-down foot-in the-grave" persons with cardiac, lung and kidney complications a generous, good full diet." He would urge i.e. such a diet on an old man suffering from frequent attacks of nose bleeding and giddiness and with a radial blood pressure of 200 millimetres of mercury—on one, in other words, with the sword of Damocles hanging over him and threatening at any moment to descend and to strike open one of the cerebral vessels. The same generous diet he would recommend (to mention some cases I have under observation at the present moment) to an aged person on the verge of uræmia, to a septuagenarian whose left ventricle is rapidly succumbing before an excessive peripheral resistance, and to an octogenarian with fixed thorax and the victim of agonising asthmatic paroxysms. Each and all of these our procrustean Doctor would subject to the same rigid routine of a full good, generous diet. No need for him to remind us that doctors disagree" They do indeed In their conception of what constitutes a correct dietary for the aged two of them at least are as widely separated as the poles

But I would not be misunderstood. I do not for one moment contend that a generous diet may not be indicated in certain cases among the old. Few indeed are the therapeutic principles that can be accepted unconditionally and I should be the last to pin myself to any rigid system, realising to the full that the physician who does this or allows himself to become the victim of a fad is in very evil case. I should not hesitate cautiously to increase and even to generous proportions the diet of a starved, anæmic old man with a low arterial pressure. I am also aware that there are cases such as those referred by D F R aged persons whose metabolism has for years been habituated to an excess of stimulating diet and for whom it is not always wise suddenly to reduce the quantity of food to slender proportions Nor do I forget that exceptional instances are met with—they are in my experience very exceptional—of old people consuming enormous quantities of food without apparent harm I myself know of a centenarian who on his 103rd birthday freely partook, among other things, of roast pork and baked potatoes, port wine, and whisky All this shows how difficult it is to dogmatise, how necessary it is to keep one's mind open, and to judge every case on its own merits But though therapeutics can never become an exact science, we should nevertheless seek to formulate general therapeutical principles for our guidance—rules of treatment which, even though they may not be universally applicable, are yet applicable to the generality of cases Such a principle is set forth in the aphorism, ' Let the diet of the aged be spare ' I believe this to be wise counsel, dictated by common sense, sanctioned by tradition, and justified by experience. I am, Sirs, yours faithfully,

Wimpole-street June 23rd 1902. HARRY CAMPBELL.

To the Editors of THE LANCET

SIRS,—In your issue of June 14th last, p 1724, you did me the honour to print a communication based on an earnestly emphasised exhortation by Dr Harry Campbell concerning a "spare diet" for the aged in his current series of articles entitled "Observations on Diet" To day (June 21st) you kindly print communications on the same subject from Dr Eric Pritchard and Dr Thomas Dutton (p 1797) Pray permit me to reply to these gentlemen through your agency

Dr Pritchard appears to be more struck with my phraseology than by the real factors of the subject under discussion in which he desires to participate There is at present no onslaught on Dr Harry Campbell—nor have I any intention of attempting one—yet, if Dr Pritchard desires to "shiver a lance" by all means let him do so and not run full tilt at me, armed with a bulrush and mounted on a donkey

Sarcasm never advanced argument yet, and a proper understanding cannot possibly be arrived at by jumping to a hasty conclusion and rushing *in medias res* simply to get one's oar in, even in the cause of "physiological feeding of the aged," which a "spare diet" is not Neither Dr Pritchard nor Dr Dutton seem to have a clear grasp of the matter in dispute, if they did they would not have succeeded in confusing the issues as they have done I am well aware of the capacity of Dr Campbell and when writing to you my disagreement with his "spare diet" dicta I was conscious of what a pitfall the phrase "spare diet" would prove to some. If Dr Campbell considered it worth his while to support his statements and had stronger reasons for his opinion than I have for mine, then he would no doubt extend and elaborate his subject—especially the terms "aged" and "spare diet." That is, if the whole paragraph in Dr Campbell's article were not to pass as a remark *en passant*, not to be taken seriously, and to be looked on as "padding" pure and simple for his article

Dr Pritchard speaks of alcohol and morphomania, and deduces from them parallels for arguing on 'physiological diet." I myself cannot see the connexion, for alcohol and morphia have further and more remote and ultimate actions over and above their immediate effect on administration They are not "food" but "drugs" Until either Dr Campbell or myself take the trouble to define what we mean by an "aged person" and "spare diet" neither Dr Pritchard nor Dr Dutton can safely intervene I am speaking of "seniles," persons well over 70—between 70 and 90—and by "generous full diet" I mean a good physiologically nutrient diet, high in proteids, carbo-hydrates, fats, and salts. Dr Pritchard and Dr Dutton seem to arrogate to themselves the right to decide what I mean and do not mean. For example, because hay and potatoes contain some small amount of proteid in their composition therefore a "generous good full diet" as used by me should of necessity correlate an elephantine meal of chopped hay or boiled potatoes in quantity sufficient to provide the necessary nitrogen. Dr Dutton, after 30 years' experience, prefers a diet "rich in nutriment substance." That is exactly what I am contending for, the more nutrient the better, though I claim to give your readers credit for understanding that I did not mean a large meal of boiled cabbage, or potatoes, or turnip tops, or chopped horse food Dr Dutton surely believes that your readers and persons to whom you accord the honour of printing their communications have some slight idea that the organs of the aged are more or less worn out, and that fermentative dyspepsia is a digestive trouble of old age I did not mention them, as I took them for granted, and was well aware that their correction and successful treatment is "part of the game" There's where the "skill" comes in. If Dr Dutton believes that "spare diet" means a diet of good nutrient quality though limited in amount, then he does not read English as "she is writ" Of course, we may now be told that that was what was meant by "spare diet." Nine medical men out of 10 in general practice interpret "spare diet' to be ' cup food," "slops,' "little or nothing during the day," "a cup of arrowroot,' a little beef tea' (*sic*), and a small piece of toast, &c Letting an old person shift for him or herself May I be permitted to call the attention of Dr Pritchard and Dr Dutton to the phrase in my letter "*full diet suitably prepared*" The only regrettable deduction from the communications of Dr Pritchard and Dr Dutton is that either they hurriedly hastened to vindicate nothing in particular, on the strength of a hasty glance at your pages (a thing never safe to do where THE LANCET is concerned as others no doubt have learned), bringing to bear on their task the least possible forethought and still less an amount of their vast knowledge and experience, or otherwise they credit me with a more profound ignorance than is usually accorded as the outcome of their everyday experience These gentlemen would, no doubt, give me credit for knowing the results of over indulgence after due proof An earnest assurance from them that they had carefully perused my article in the *British Medical Journal*, Oct 13th, 1900, and a search and verification of the references given—a task which occupied me for six months—would have made me more disposed to consider their "defence" of Dr Campbell as really serious

I am, Sirs, I trust, quite conversant with "metabolism" and with the terms 'anabolism' and "katabolism," also with that "blessed word" auto intoxication, together with their theoretical results, as the armament of the diet specialist. I had hoped that my parenthetical mention of lung and kidney disease would have spared me their being flung at me by Dr Pritchard—for which much thanks Complications of old age (from 70–90) are only those complications peculiar to senility, and anyone really conversant with my subject would not drag into the discussion the results of previous riotous living—though even they can be successfully dealt with as part of the "game." Aging as we see it, is nature's mode of killing, and in order to assist the process she calls in weak digestion, loss of teeth, liver, kidney, lung, and heart disease When the disease complications are the result of fair hard wear and tear they can be restored by "good full generous diet," to a surprising extent The medical man who plays nature's game for her by "spare diet" simply because there are "kidneys," "liver congestion," "cardiac failure," &c., is very like that general who "marched his men up a hill and marched them down again" because there were persons on the top likely to dispute with him its possession. Rather is it better to flank or enfilade the position than to retreat because of the opposition This retreat the "spare diet" treatment closely imitates I have ever noted that your medical scientist, well versed in the "bolisms" and autoisms and what not, is in the end usually found pleading the excuse in justification for his failure in treatment, especially where the very aged are concerned, "Oh, you see, he (or she) was so old, you know", "Quite worn out", "You see, the heart was literally used up", "Run to a standstill," &c. That man was running the "spare diet" ticket, had he run the good, full, generous diet (I don't mean feeding to repletion), suitably backed up therapeutically, he would most probably have got another five to seven years out of his patient I am not "done for" yet, Sirs, and remain yours faithfully, F W FORBES ROSS, M.D Edin

June 21st 1902.

THE MIDWIVES BILL

To the Editors of THE LANCET

SIRS,—The Lord Chancellor made it clear in his speech on the second reading of the Midwives Bill on June 20th that though not unfriendly to the Bill as a whole he disapproves of the provision (Cl. 1) that *after the year 1910 no woman shall habitually or for gain attend women in childbirth unless she be certified under this Act* " If this provision is left out no protection whatever will be given to the public against the most dangerous class of untrained women who will be just as free to practise as they are at present, so long as they call themselves by some other name than midwife. The safeguard afforded by the Bill would be very slight, though undoubtedly a step in the right direction. The Lord Chancellor suggests that those who drew up the Bill had in their minds large centres of population and had not considered the case of thinly populated districts where trained assistance would be hard to get. But we maintain that the very scarcity of medical help in rural districts makes it the more necessary that skilled midwives should be available, and as long as untrained women are allowed to habitually practise it is useless to look for an adequate supply of competent ones.

During the eight years that would elapse before this provision comes into force there would be ample time to organise and increase the means of midwifery training all over the country The Lord Chancellor points out that as a rule the midwife in country districts acts also as maid of all work in the house during the mother's illness. That is in very many cases true, and it is surely another reason for insisting that she should have a certain amount of training and a knowledge of the paramount necessity of antiseptic precautions in the sick room. Many are the cases in which fatal injury has been done to mothers by women coming direct from field labour or various uncleanly occupations to attend them in childbirth and it is well known that want of cleanly attention at birth is the cause of a large proportion of the cases of blindness and impaired sight in this country Being trained as a midwife would in no wise prevent a woman from carrying on other avocations in the intervals between her cases. It is often forgotten that the word habitually in this clause leaves a wide margin for freedom of action in cases of emergency or for the individual preference of patients. Anyone could still freely go to the help of a neighbour in distress a mother could nurse her daughter or friend go to friend if for personal reasons or in sudden cases the midwife was not to be had But we maintain that if any persons habitually undertake this work ample cause has been shown why they should be obliged to duly qualify themselves for it.

We believe that much of the opposition that has been shown to this clause is due to the fact that people imagine that all friendly aid from one neighbour to another will be put an end to. That this fear is unfounded the above explanation will show That, also we think may be at the root of the objection of the clergyman quoted by the Lord Chancellor who said there was very serious objection to the Bill on the part of the working classes. Wherever to our knowledge meetings have been held and the details of the Bill laid before them the very strongest feeling in favour of it has been manifested and many and very numerously signed petitions from working men and women have been sent to the House of Commons in favour of this legislation.

of Midwives, July 1902.

THE MEDICAL SERVICE OF THE MERCHANT MARINE

To the Editors of THE LANCET

SIRS,—With reference to a letter in your issue of June 28th, p. 1857 from Dr W T Burres *re* the position social and financial of surgeons in the merchant service I should just like to say how thoroughly I agree with Dr F B Ryan s answer in THE LANCET of July 5th, p 45. As a former surgeon in the P & O Company and speaking of the ship surgeon s lot from that standpoint, it has always appeared to me ever since I joined the company that a ship surgeon has singularly little at which to grumble The position never seemed in any danger of being lowered in the eyes of either passengers officers or crew and from my own experience and that of other P & O surgeons if a man did find himself given the cold shoulder it was almost a certainty that it was his own fault. The pay was £10 a month and no one need grumble at that, especially if he only thinks for a moment that in addition one was seeing the world or a good part of it, meeting as good men as ever one could wish to meet, being lodged and fed at least as well as the most fastidious could require and (here most men will bear me out) doing work that, as a rule, might have been a good deal heavier without unduly taxing one's energies.

The average man who, looking back on the days when he was ship surgeon, can honestly say that he is sorry he ever went to sea or that he did not have a good time when there has only himself to thank for the character of his reflections. In isolated instances events have occurred at sea which have coloured a man s whole life unfavourably, but these are exceptions and taking the general run of things the ship surgeon who does not thoroughly enjoy his time has to thank either his physical or social disposition

Dr Burres calls ' steamship doctors a 'most abject class of practitioners. If a man is abject at sea he will be equally or more so ashore so there would seem little chance of the profession benefiting by the return of those gentlemen to civil or shore life if Dr Burres is right, which I venture to deny in his estimate of their character My memory of happy times as a ship surgeon and my possession of good friends gained while acting in that capacity will perhaps excuse my troubling you with this letter

I am, Sirs, yours faithfully
ANDREW B BLAIR, M.B C M Edin.,
late P & O S N Co
Eversleigh Banwell Somerset, July 5th 1902.

PRECOCIOUS CONCEPTION

To the Editors of THE LANCET

SIRS,—With reference to an article on the above subject which appeared in THE LANCET of June 7th, page 1601, I may say that in October 1883, I attended in labour a girl who was born at the end of the year 1868 and delivered her of a living mature male child The case occurred in a hamlet some miles from here, the patient being in charge of the local *sage femme* The age of the child mother was 14 years 10 months. She made a good recovery and for aught I know the child may still be living While writing I may state that in May 1897 I delivered a married woman who gave her age as 50 years, of a living child having however to use the forceps to do so These two cases demonstrate the youngest and oldest mothers in my obstetric experience By reference to Guy s Forensic Medicine I find several cases recorded in which the mothers were younger and older than those I have mentioned.

I am Sirs, yours faithfully,
O. H. L. JOHNSTON M D L R C S. & L.M Edin.
St. John N B Canada June 24th 1902.

A NEW METHOD OF KEEPING IN APPOSITION THE EDGES OF SURGICAL INCISIONS AND WOUNDS IN ORDER TO PROMOTE UNION

To the Editors of THE LANCET

SIRS,—In reply to Mr J MacMunn s letter respecting A New Method of Keeping in Apposition the Edges of Surgical Incisions and Wounds in order to Promote Union " I beg to suggest that he cannot have read carefully the description of the appliance which I gave in THE LANCET of June 28th, p 1839 nor can he have noted particularly the method of inserting it. There is just that difference between my appliance of to-day and the one introduced by Mr MacMunn 18 years ago that makes all the difference " The structure of the former enables it to be driven into the flesh with astonishing ease, *not as one would push in two parallel and ordinary curved needles but by a rotatory movement upon the centres of the semicircular prongs* and thus the points should never protrude through the flesh.

Unfortunately no illustration or letterpress can give anything like an adequate idea of the facility with which my appliance can be introduced and withdrawn once the knack has been acquired. More than one of the distinguished surgeons who have done me the honour of manipulating it have at once perceived that a certain knack is necessary which is instantly acquired when seen Mr MacMunn may at first sight see some resemblance between his design and mine, for all clamps may be more or less alike But his requires a cork to be placed over the protruding points after insertion—a clumsy, unscientific, and impossible method, as the past 18 years have eloquently demonstrated. However, I shall shortly have some results of trials that are now being conducted in some of our largest London hospitals to submit to those who may be sceptical, and in the meantime I shall be most happy to demonstrate the application of the new clamp by the side of Mr MacMunn's before any unquestionable surgical authority he may select.

I am, Sirs, yours faithfully,

HAYDN BROWN, L R.C P Edin

Surbiton, July 6th, 1902.

THE SEED AND THE SOIL

To the Editors or THE LANCET

SIRS,—The admirable and instructive lecture and leading article which appeared in THE LANCET a few weeks ago[1] have brought the "seed and the soil" subject before your readers in a way calculated to impress the memory with some sound and useful facts No doubt in the growth, spread, and fatality of disease, especially of epidemic diseases, the soil or the bodily state has more to do with the untoward results than the quality of the seed sown If the body or soil is in a healthy, robust state the seed sown fails, but if the body is in a state of cachexy or low vitality the soil may bring forth some a hundredfold, some sixtyfold, some thirtyfold But the resisting or receptive power of the body or soil depends for the most part on the climate or locality in which it is situated If the climate or locality is all that can be desired from a sanitary point of view the soil is healthy and resists contagion, but if otherwise the body or soil lies open to receive the seed or microbe of disease wherever it comes from And of all the preventives of disease there is none that can be compared to a good and perfect drainage of the environments of the soil or body

Before the main drainage of Lincoln was effected its sanitary state was as bad as it could be The sewage ran into cesspools and there was allowed to ferment and to putrefy and to fill the air with noxious effluvia. Dysentery, diarrhœa, and typhoid fever prevailed and consumption was so common that Dr Thompson of the Brompton Hospital for Consumption, in his Clinical Lectures on Pulmonary Consumption, remarked on it. The disease was most frequent among women who remained at home in their houses, but their husbands who spent their days away from home in the fields generally escaped contagion. When the main drainage was accomplished a rapid improvement in the health of the city took place and now in this "coronation year" typhoid fever and consumption seem to be dying out, and although we have recently had a slight outbreak of scarlet fever, still the death rate is only about 14 in 1000, and I hope that when the sower goes forth to sow the seeds will fall by the wayside and the fowls of the air will come and devour them up —I am, Sirs, yours faithfully,

WILLIAM O NEILL, M D Aberd , M.R.C P Lond.

Lincoln July 5th 1902.

INSANITY AND THE DEATH PENALTY

To the Editors of THE LANCET

SIRS,—My attention has just been drawn to an article in THE LANCET of June 21st, p 1782, with reference to the trial for murder of the unhappy man Simmons at the recent Dorset assizes, and I shall be glad if you will allow me to say a word in reply upon the facts of the case which may be of interest to your readers from a scientific point of view, as well as a matter of fairness to the prisoner The writer has picked out the salient facts without reference to any of the minor events which qualified them, and upon these facts he has assumed that the theory of the prosecution that this was a deliberate crime "committed by an angry man upon a woman who had refused (apparently) to respond to his passion" was proved, but this is exactly what the prosecution utterly failed to prove, and it was obvious to everyone who heard the evidence that the suggested motive for the crime was absolutely broken down and for ever gone long before the close of the prosecution, and I have the authority of Dr Weatherly and Dr Morton for saying that unless they had been previously satisfied of the untruth of the theory of the prosecution and of the consequent want of motive for the crime they could not have expressed the confident opinion on the case which they did in the witness-box.

I am, Sirs, yours faithfully,

A. WENTWORTH MALIM,
Solicitor for the Defence.

Weymouth, July 2nd, 1902.

THE PUBLIC HEALTH SERVICE AND THE CORONATION HONOURS LIST

To the Editors of THE LANCET

SIRS,—While agreeing generally with your admirable leading article on the Coronation Honours in THE LANCET of July 5th, p 31, and while also fully endorsing your statement that "the general design of the Crown, and of the advisers of the Crown, appears to have been to do ample justice to workers in the cause of humanity at large," may I venture to draw attention to the altogether remarkable omission from the honours list of that great service of the State which is responsible for the health of the people? This service through its untiring efforts is instrumental in saving annually thousands of lives It is gradually prolonging the average duration of life on the planet, and, by improving the physical conditions under which the poor live, it is carrying on a work which has no parallel in history This service exercises a leavening and altogether non-political influence throughout all grades of society, and the force which it represents is, perhaps, if read aright, the most far-reaching anti revolutionary power of modern times Nevertheless, this service has received no recognition whatever in the recent honours list

Perchance, had the victories of preventive medicine in Great Britain been less complete, and had bubonic plague invaded our shores, and small pox spread broadcast over the land, the conditions would have approximated more to those of the field of battle, and decorations might have been bestowed upon the service on almost military lines It may possibly be that the martial spirit of the moment has led the advisers of the Crown to attach less importance to the saving of human life and to the improvement of its conditions But whatever the explanation the omission is none the less remarkable

It would be obviously absurd to suppose that the monarch who happily still reigns over us, and with whose name the pregnant query, "If preventable, why not prevented?" will always be associated, would have allowed this omission had the claims of this service been adequately put before him. The deep interest taken by His Majesty in the housing of his poorer subjects and in the prevention of tuberculosis and cancer is sufficient in itself to negative any such view Moreover, I read the signs erroneously if I do not detect in the list of honours the keenest sympathy of King Edward VII for the worker whatever such work may be. In this sense the honours list is in my opinion, altogether unique. Nor can I believe that the able and vigorous Cabinet Minister who is responsible for the sanitary service of this country has failed to lay before the proper authorities the claim of those who, in the prevention of plague and small-pox, and in the routine work of public health have so well supported his efforts Mr Walter Long must, above all others, be aware of the signal services rendered to public health by the labours of his own medical department, and by those numerous medical officers of health who in our ports and towns have borne the brunt of the attack.

But there is something strangely anomalous in the fact that honours should have been showered, and justly so, upon those who have defended the honour of the Empire in the battle field while those who in the paths of peace have kept disease from our shores, and have made the name of England synonymous with sanitation should upon a historic occasion such as this have been passed over in silence. If, Sirs, it were possible that on each New Year's Eve, as the ebbing year flows into the ocean of time, there should be a march past of all those men, women, and children whose lives preventive medicine had saved during that year, a spectacle would be witnessed which would cast martial displays into relative insignificance, and which would awaken in the minds of the onlookers some conception of the work done quietly and unostentatiously by the medical officers of health throughout the country

---

[1] THE LANCET May 10th (p 1297) and June 28th (p 1843) 1902

I am, Sirs, yours faithfully,

July 7th, 1902.　ANTITOXIN

To the *Editors of* THE LANCET

SIRS,—In the concluding sentence of the leading article in THE LANCET of July 5th, p. 31 you refer to the list of naval and military honours, so far as they affect medical departments as completing a gratifying total of distinctions accorded for public services to the profession But surely exception may be taken to that view inasmuch as not a single honour has been bestowed on "the service" which is specially devoted to civil sanitation administration, and public health

It will be remembered that His Gracious Majesty in his famous speech at the International Congress in 1891 showed how desirous he was of encouraging not only the scientific study of the causes of diseases but also what is at least equally important, the application of existing knowledge to the public benefit through improved methods of administration The last 25 years may be said to have been very conspicuous in the annals of preventive medicine by the development of this work and the gradual formation of a department which in a wide sense may be said to be of great practical value distinct from that of the Local Government service generally If we only consider the services rendered in connexion with some of the epidemic diseases most dreaded in this country—cholera, small pox, and plague for example—there is surely enough to justify the claims to distinctions and rewards of a body of professional men who have sacrificed many opportunities of pecuniary advantage besides incurring special risks and who bring to their work literary and scientific attainments together with official zeal, tact and discretion It should, however be insisted that it is not on exceptional occasions only but in the daily life of every great municipality or district, that the above-mentioned services are of great and immediate practical importance. It needs a long and intimate knowledge of our Local Government system to appreciate fully the essential value to the public of fairly well placed medical and sanitary officials. Vast sums of money are year by year loaned to and expended by sanitary authorities In the direction and control of this expenditure the important assistance already rendered by able and experienced medical officials ought in simple justice to be recognised. For this reason alone, and purely as a matter of public policy it is time to protest against the Service being continually ignored. It is, indeed hardly conceivable that His Majesty would not have considered the claims of the civil sanitary medical service had they been properly explained.

It is now more than half a century since medical officials began to serve the State, municipalities, and local authorities generally and yet during the whole period of ceaseless and growing activity not more than five or six titular distinctions have been conferred for public service of this kind.

I am Sirs yours faithfully

July 7th 1902.　ADMINISTRATOR.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Subsidence of the Plague Epidemic —Training ship for Eurasian Lads —Sewage Schemes for Bombay —Suburban Drainage for Calcutta

DURING the past fortnight there has been a marked decline in the plague mortality throughout India. On June 4th 4214 deaths were recorded but on June 18th only 1316. It is a long time now since the plague mortality touched such a low point. Although greatly lessened the disease still clings to the same infected districts The detailed figures for the past week are Bombay City 82 deaths Bombay Presidency 169 Karachi 35, Madras Presidency 12 Calcutta 65 Bengal Presidency 37, United Province 33 the Punjab 776 and Mysore, 103. The plague has never been very severe in the Madras Presidency but it sticks there as tenaciously as in other places.

A very excellent scheme is on hand promoted largely by Dr J R. Wallace of Calcutta, for establishing a training ship for Eurasian lads. This if successful will provide an outlet for a considerable number of the boys of this community who are now handicapped in many ways in getting employment, and moreover it will provide a training for them which will correct some of their Indian native habits. It will be still further useful as an ultimate recruiting ground for the mercantile marine.

Some very important sewage schemes are likely to be carried out in Bombay These concern the Malabar Hill district on the south and west, and some villages on the north and east of the island. It will be remembered that for part of Bombay City the Shone system is in force and it was at first proposed to extend this system to the Malabar Hill district It is now proposed to divide the district into three portions. One is to have the Shone system a second is to have the sewage treated biologically and the third will be drained partly by an arrangement of lifting the sewage into a gravitating station Most interest centres in the proposed septic tank which will be located near the foreshore. It will serve a population of nearly 6000 and 300 000 gallons daily of sewage flow are calculated for The sewage will first discharge into a closed septic tank and will flow through at the rate of a few feet per hour The effluent from the septic tanks, in which 80 per cent. purification is expected, will flow on to a series of six bacteria beds for final purification. The effluent will remain in these beds for from two to six hours according to the daily level of the tide. The resulting final effluent is expected to be free from any suspicion of sewage contamination. The gas from the septic tank will be used for lighting the installation at night. It is estimated to cost about £20,000 Some of the villages will be drained by open sewers as gradients for closed pipes are not possible and the sewage will be treated first by an open septic tank and afterwards on a sewage farm. It has previously been found at the Matunga sewage farms that one acre of land can successfully dispose of 5000 gallons a day Crops will be grown of lucerne and all kinds of vegetables. It is considered probable that the proposed farm will prove a paying concern. These schemes are the work of Mr C C. James who has been so successful with the biological treatment of sewage from the Matunga Asylum. The municipality of Calcutta is also very busy with its suburban drainage This was designed in 1896 and was made of larger diameter than if required for the drainage of sewage only There is a great conflict of opinion. The sewage is to be discharged from the high-level sewer into a tidal channel at a point about a mile distant from the inhabited parts of the town whence it will be discharged into the river by tidal action alone. The whole scheme is admittedly experimental and some authorities do not hesitate to foretell disaster A point hardly sufficiently considered appears to lie in the strong tides and great changes of level in the river Hoogly and I am not at all sure that this will not prove a danger to the sanitary condition of the river opposite Calcutta.

June 20th

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT)

The Coronation Honour to Professor Oliver J Lodge

THE liberal recognition of the medical profession in the list of Coronation honours has been received with much gratification while the rewards of merit which have fallen to distinguished men of science associated with medicine in many ways have also given the profession pleasure. The knighthood of Dr Oliver J Lodge, the Principal of the University of Birmingham is a case in point. Dr Lodge came to us two years ago from Liverpool where his splendid work for 10 years at the University College in that city had gained for him exceptional reputation as a pioneer in electrical research. In Birmingham his distinction is welcomed as a just tribute to his attainments as a contributor to scientific progress and as an able organiser and administrator in the new university

The Deaf and Dumb Institution

Among the valuable institutions in our midst few commend themselves more strongly to the benevolent public than those connected with the training of the deaf and dumb Yet even here the need for greater pecuniary support is felt. The annual meeting of the Deaf and Dumb Institution was held on June 19th, when the report stated that the ordinary expenditure was £7321 and the income £6200 The education of the children is provided for as a necessity under the Deaf and Dumb Education Act which has been in force for about eight years, it compels every child to be educated and in this institution the training is efficient and complete. By means of the apprentice system suitable training is provided and work is found for the pupils, so that their abilities can have full play The King has kindly consented to be a patron of this institution and every effort is being made to increase the income

Accidents in Birmingham

The rejoicing at the time appointed for the Coronation was in many cases not discontinued, though it might be chastened, on account of the serious illness of the King The occasion had been set apart as a time for jubilation, work had been discontinued, and there was an evident intention on the part of many to behave as if the holiday had been undisturbed. As a result there were numerous accidents to record in Birmingham At the General Hospital during 24 hours there were 75 casualties dealt with on Coronation Day and the same number on the previous day At the Queen's Hospital some 60 cases were dealt with during a similar period of 24 hours, all being more or less serious accidents and injuries The placing of lines for decorations so low down in the smaller streets that drivers and passengers on vehicles were caught by them in driving through the districts was responsible for several unpleasant injuries, leading to a protest by the coroner during the sitting of his court.

Hospital Sunday Fund in Birmingham

The annual meeting of the promoters of this fund was recently held to appoint a committee and arrange for this year's collection The date was fixed for Oct. 26th It was pointed out that since the fund was instituted £203,000 have been handed over to the medical institutions and charities of Birmingham, and a desire was expressed that no efforts should be spared to make the collection worthy of the occasion this year

Hospital Saturday Fund in Birmingham

The collection by this organisation is a splendid example of what may be done by well directed and systematic efforts In the principal workshops and factories of the city a collection is made week by week from the employés on behalf of the medical charities of Birmingham and the four convalescent homes belonging to the contributors to the fund. Saturday, June 14th, was set apart for the total amount to be handed in to the fund The street collection this year was wisely discontinued. A sum of £15,930 7*s* 8*d* has been received and it is expected that when the accounts are made up the year will be a record one

July 8th

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Liverpool Stanley Hospital Critical Condition

THE finances of the Stanley Hospital are considered to be in a very critical condition At the end of 1901 the debt on the institution was £5000 The worst feature of the matter consists in the fact that the expenditure exceeded the income by £1700 It would probably not be difficult to clear off the existing debt by a special effort on the part of the committee, but there is no concealing the fear that, unless the annual subscription list be considerably enlarged the hospital, or the greater part of it, may have to be compulsorily closed. At present 20 beds out of 80 are unoccupied, not because there is no demand for them, but because of the poverty of the charity The Stanley Hospital is situated in the poorest part of the city and is doing admirable work Last year the number of attendances of out-patients was 56,952. Only a statement of these facts is needed to bring out a liberal response to the appeal of the committee for funds in order to avert the catastrophe of closing an institution which has done so much good for the poor of the north end of the city The hospital has had a very good surgical record, and no less than five members of its honorary staff have been promoted to honorary posts at the Royal Infirmary

The African Association and the School of Tropical Medicine

The African Association, Limited, has given a further grant of £100 to the Liverpool School of Tropical Medicine

The Home for Epileptics at Maghull

At the annual meeting of the Home for Epileptics at Maghull it was stated that £800 were still required to enable the committee to claim the £1000 promised by Sir Alfred L Jones, conditionally on a further £9000 being raised, for the purpose of providing land to give employment to patients who had been trained to work and of extending the accommodation generally Towards this deficiency Sir Thomas Brocklebank has liberally supplemented his previous generous benefaction by contributing £250 The amount required is thus reduced to £550, and the committee is making a strenuous effort to prevent Sir Alfred Jones's generous offer from proving abortive.

The Coronation Honours

Dr Oliver J Lodge, F R S, one of the recipients of the honour of knighthood in the Coronation honours list, was appointed Professor of Physics at University College, Liverpool, in 1881 He held that position until 1900, when he became the principal of Birmingham University Dr Lodge has made important researches into the nature and properties of ether These contributions to science gained for him the honour of a Fellowship of the Royal Society —Major Ronald Ross, F R.S, late I M S, upon whom the distinction of a Companionship of the Bath (Civil) has been conferred, was for some time director of the Liverpool School of Tropical Medicine He conducted an important series of expeditions in the West Coast of Africa to investigate the origin of malaria. Major Ross is chiefly responsible for the investigations which established the association between malarial fever and mosquitoes In 1881 he entered the Indian Medical Service The special study of the life-history of malarial parasites was begun by him in 1892.

Proposed Sanatorium for Tuberculosis for Cheshire

The health committee of the Cheshire County Council has reported favourably on the desirability of establishing a sanatorium in Cheshire for the treatment of patients suffering from tuberculosis resident in that county Liverpool possesses a splendid institution of the kind at Delamere Forest, but Cheshire patients have scanty prospects of admission to that institution owing to its crowded condition

National Union of Sanitary Inspectors

The sixth annual conference of the National Union of Sanitary Inspectors was held in Southport last week Mr William Daley, chief sanitary inspector of Bootle, read a paper entitled, "Are the methods of disinfection as usually carried out by sanitary authorities efficient?" He asserted at the outset that the way in which disinfection was carried out rendered the work of dealing with infection abortive, and that men engaged in the prevention of the spread of disease were sometimes active disseminators of infection by transmitting the disease through their infected clothing Mr Bland (Urmston) Mr Pears (Wolverhampton), and Mr J J Weaver, the medical officer of health of Southport, took part in the discussion which followed, the latter advocated the old fashioned sulphur disinfectant

July 8th

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS)

Cottage Hospitals for Monmouthshire

THE question of establishing a cottage hospital at Tredegar in Monmouthshire has been under discussion for many months, and the workmen employed at the Tredegar collieries and ironworks have at length decided by ballot to contribute one halfpenny a week each towards the maintenance of the institution. By this means nearly £400 yearly will be raised. Lord Tredegar has given a site adjoining a large public park, and it is proposed to erect a building to cost about £2000 —At New Tredegar a hospital is to be erected and the whole cost of the building will be defrayed by the Powell Duffryn Colliery Company, while the maintenance and management will be in the hands of the workmen in this instance also the site has been presented by Lord Tredegar

Habitual Vagrants

As long ago as 1895 the master of the Ledbury workhouse suggested to a conference of Poor law guardians assembled at Malvern that farm colonies should be established to which habitual vagrants could be sent and detained and set to work. The Poor law Unions Association has now suggested a scheme embodying this principle and on June 20th the Bristol board of guardians supported the proposal of the association but expressed the opinion that the cost should be borne by the State rather than by combinations of unions. The scheme is briefly this—a vagrant found for the third time in a particular casual ward would be sent by a magistrate to a labour colony and detained there for a period of not less than one year and not more than three years; the vagrant would be given a percentage of his earnings at the time of his discharge and if there was evidence of his having acquired regular and industrious habits he could be let out on licence prior to the expiration of the period of his detention, able-bodied inmates of workhouses could be sent on the order of a magistrate to a labour colony, and the colonies would be classified according to trades and a labour bureau would be established in connexion with each colony The Bristol board of guardians considers that the 'way ticket system adopted in Gloucestershire and for some time in Berkshire should be made universal, so that *bonâ fide* working men travelling from one centre to another in search of work could be identified and separated from idle wanderers in the workhouses at which they called.

Brentry Home for Inebriates

At the meeting of the Somersetshire County Council held on July 1st it was decided on the casting vote of the chairman to contribute an additional sum of £250 to the Brentry Home for Inebriates. During the discussion of the question there was considerable difference of opinion as to the usefulness of the institution in which there is now accommodation for 200 patients and which has for the past six months been able to pay its way Mr Warry K.C said that his experience of 30 years in the administration of criminal justice of every form led him to think that inebriates homes were not worthy of their contribution. while Sir Edward Fry on the other hand advised the council to continue to support the home the reports from which showed that it was doing good work.

Mr Andrew Carnegie's Libraries.

Mr Andrew Carnegie has presented £2000 to Bridgend for the erection of a free library £6000 to Merthyr for a central library and six branch libraries, and £8000 to Barry for a central library In the case of Barry it has been the intention of the district council for some years past to expend £2000 upon a library building and if this sum is now utilised in the erection of a much needed small pox hospital Mr Carnegie's gift will have an added value. Is there no millionaire who could be persuaded to scatter isolation hospitals over the country as Mr Carnegie is distributing free libraries?

Health of Cornwall.

The sanitary committee of the Cornwall county council in its annual report for 1901 which has just been issued states that the population of the county is estimated at 322,808. The births numbered 7902, corresponding to a rate of 24 47 per 1000 The deaths amounted to 5154 giving a death rate of 15 96 per 1000 291 deaths were caused by cancer being 28 in excess of those in 1900 The mortality from consumption was stated to be 1 49 per 1000 as compared with 1 38 in the preceding year

Vaccination Expenditure

At the meeting of the Chepstow board of guardians held on July 3rd the vaccination committee presented its report upon the fees paid to the public vaccinators. The amount of these fees being considered excessive a committee was appointed to go into the matter but instead of being able to suggest any reduction in the fees it recommended increasing them in four districts The committee stated that in two districts the public vaccinator had been only charging 6*s* 6*d* per case whereas he was entitled to 8*s* The committee pointed out that the public vaccinators had often to go three, four and even six times to the people's houses, for it was most unusual for two visits to suffice, and there was also a large amount of clerical work. The guardians, after some discussion during which the Vaccination Act was much condemned by some of those present, decided to follow the recommendation of the committee and also to pay the public vaccinator the difference of the fees which he had undercharged.—At the meeting of the Devonport board of guardians held on July 4th a considerable discussion took place with regard to the question of revaccination fees It was pointed out that in the opinion of counsel those who published the names of persons who had been revaccinated might get themselves into trouble for the Vaccination Act was intended to apply to all alike both rich and poor Eventually the following motion was carried —

> That requests be made for repayment of fees by those who in the judgment of the Finance Committee, are in a position to pay

At the meeting of the Penzance board of guardians held on July 3rd it was reported that the cost of revaccination during the past six months amounted to £83. One of the guardians moved that all the guardians should do all in their power to get the Vaccination Act amended. After some discussion this was carried.

July 8th

PARIS

(FROM OUR OWN CORRESPONDENT)

The Treatment of Addison's Disease by Injections of Suprarenal Extract

AT the meeting of the Therapeutical Society held on June 25th M Hirtz read notes of two cases of Addison's disease in which recovery had followed the use of suprarenal extract. One patient in addition exhibited definite tuberculous pulmonary lesions and these healed rapidly under the treatment. Encouraged by these results M. Hirtz has tried the drug in other tuberculous affections and these cases also appear to be doing well.

Medical Institutions in Madagascar

At the meeting of the Academy of Medicine held on July 1st M. Kermorgan read a report upon recent medical organisation in Madagascar General Galliéni started a medical school 16 hospitals five lazar houses a maternity hospital and four infirmaries. By the end of 1902 there also will be in working order 10 hospitals, one lazar house, a lunatic asylum, and a sanatorium for tuberculous patients The Malagasys's notions of hygiene leave much to be desired for they neglect the most elementary rules on the subject and personal cleanliness is almost unknown among them Some of their customs are deplorable—for instance they keep their dead three or four days before burial during which time they hold a regular wake accompanied by a gorge of food and alcohol. Once a year too they visit the tomb take out the corpse and change the grave clothes The houses are badly built and badly ventilated the ground floor being shared in common by cattle and men. Among the most frequent diseases are malaria, tuberculosis leprosy, and alcoholism. In order to fight against this last scourge General Galliéni begs all officials and soldiers to set an example of moderation.

The Residents at the Lariboisière Hospital

Last March relations between the Assistance Publique and the resident hospital officers (*internes*) became very strained. The latter whose pay varies from 50 to 80 francs per month asked the faculty that they should not be compelled to live in the hospital but should receive instead the allowance of 50 francs per month to which they are entitled by the regulations of the Assistance A special committee was appointed to inquire into the matter and this committee reported that the old system should be adhered to seeing that the interests of the patient demanded that some one should always be on duty in the hospital. Fresh difficulties have now arisen between the resident officers of the Lariboisière Hospital and the authorities of that institution. The residents have just given up attending in the duty room They have moreover written a long letter to M. Mourier the Director of the Assistance Publique in which they set forth certain grievances which they have against M. Faure the director of the hospital. They maintain that the only way out of these difficulties is that they should be allowed to live outside, coming in with the surgeon or physician of the day and also making the usual round of the wards in the evening They also ask M Mourier to see that the men on duty in the hospital should have *déjeuner* or dinner according to their period of office. M. Faure declares that all this to do is owing to females having been forbidden entrance to the duty rooms. This rule was recently made obligatory on all the hospitals, but M Faure was the first to carry it out.

July 9th

CANADA

(FROM OUR OWN CORRESPONDENT)

Ontario Medical Association

ONE of the most successful annual meetings of the Ontario Medical Association was that which was held in the city of Toronto on June 4th and 5th. Nearly 200 medical practitioners were present, all sections of the province being represented, and as evidence of the interest taken in this association fully two-thirds of the papers were contributed by physicians residing outside of Toronto Dr Newton Albert Powell, the president of the association, occupied the chair, while Dr Harold C Parsons, also of Toronto, discharged the duties of secretary Dr John T Fotheringham had charge of the committee on papers and business and Dr J Milton Cotton, also of Toronto, of the committee on arrangements

Six excellent papers were read at the morning session of the opening day Deformities Consequent upon Injury, either Traumatic or Pathological, to the Epiphyseal Cartilages, in Long Bones, by B E McKenzie of Toronto, Some Points in Life Insurance, by John L. Davison of Toronto, Transplantation of the Omentum into the Abdominal Wall for the Relief of Ascites due to Cirrhosis of the Liver, by George A. Peters of Toronto, The Cure of Chronic Bright's Disease by Operation, by Alexander Primrose of Toronto, Tonsillar Hypertrophy, its Operative Treatment, and the Comparative Value of the Different Methods, by Perry G Goldsmith of Belleville, and Some Comparative Results of the Medical and Surgical Treatment of Appendicitis, by J P Armour of St. Catherines All these papers were provocative of interesting and valuable discussions, especially that on life assurance by Mr Davison. As medical director of a large Canadian life assurance company Mr Davison emphasised the importance of medical examiners making accurate returns of their examinations, pointing out at the same time that it would be of very great service to the medical director of any company if examiners would send them a private letter on the condition of the applicant, which letter would always be held strictly confidential Mr Davison gave some interesting statistics showing the amount of money which insurance companies were paying annually to the medical men in the United States and also in Canada. The discussion turned mainly upon the fee paid for such examinations, the consensus of opinion being that three dollars for a minimum policy was too small, it ought to be at least five dollars. Another paper which was listened to with a good deal of attention was that by Dr Peters on the transplantation of the omentum Dr Peters exhibited this patient, a man, apparently 50 years of age, who was now seemingly in sound health Photographs were exhibited showing the enormous abdominal distension prior to operation, and in illustrating this still further Dr Peters got his patient to draw on a pair of pantaloons which he had worn when his abdomen was distended. The waist-band of these trousers measured 64 inches

On the assembling of the meeting in the afternoon Dr Powell delivered the annual presidential address The points mainly touched upon had relation to the medical legislation before the Ontario Legislature and the Dominion Parliament at their last sessions respectively Regarding the attempt made to reform the Ontario Medical Council by the elimination of the homœopathic and college representatives from that body, the President stated that he had considered it his duty as chief executive officer of the association to oppose that legislation because it was not fair, having once made an honourable bargain with the homœopaths, to cancel it *in toto* without as much as saying "by your leave." Referring to the measure for a Dominion Medical Council, so successfully promoted and carried through the Dominion Parliament by Dr Thomas G Roddick, M P, he thought the Bill had been so emasculated that it was now practically a measure for neither very much good nor very much evil. The amendment to the Canada Evidence Act providing in medico legal cases for a board of expert witnesses from three to five in number he considered a move in the right direction.

The regular business being again resumed, Dr J Algernon Temple, Professor of Obstetrics in the Trinity Medical College, Toronto, presented a paper on Ventro Fixation, its Value and Results. Dr Temple condemned this operation which he considered both impracticable and unscientific The meeting here divided into sections. In the Obstetrical section the following papers were read and discussed Placenta Prævia, by H D Livingston of Roacwood, How Best to Meet Obstetric Emergencies, by C J C O Hastings of Toronto, Notes on Five Cases of Ectopic Gestation, by R B Webster of Ottawa, and the Treatment of Septic Abortion, by Kennedy McIlwraith of Toronto In the Medical section the following were the papers Pneumonia, by David Hoig of Oshawa, The Treatment of Pneumonia, by J C Mitchell of Enniskillen, A Recent Epidemic of Cerebro-Spinal Meningitis, by Alexander McPhedran of Toronto, Primary Tracheal Diphtheria, by R. D Rudolf of Toronto, Where can our Consumptives Best be Treated? by J H Elliott of Gravenhurst Sanatorium, and Pleurisy with Effusion, by D. Gilbert Gordon of Toronto

"Medical Testimony in Courts of Law" was the title of an interesting and timely address delivered at the opening of the evening session by His Honour Judge MacDougall of the County Court, Toronto His Honour pointed out how conflicting medical and other expert testimony often was, which he considered arose chiefly out of the method of securing and employing such witnesses For this he suggested the remedy which would make the expert an assistant or adviser to the court And their reward should not depend upon the parties in the suit but should be provided by the State He considered that the new Act limiting experts to three, or five if asked for before the trial began, was a move in the right direction He urged medical men to give their testimony in popular and not in technical language Mr I H Cameron, M.B Toronto, discussed the paper Mr Cameron has had a great experience as a medical expert and his opinions were listened to with great interest. He thought that the popular criticism of the experts was a harsh one, because the public did not understand the difficulties under which the experts worked, as they were not testifying upon facts but simply giving opinions on facts He considered that unanimity could not be expected in the present state of medical science, which rendered two views possible and likely in every case All medical men would welcome any such change in the law as that suggested by Judge MacDougall Then followed a paper on the Status of the Hospital Interne in Ontario, by Dr H. S Hutchinson, himself a resident of the Toronto General Hospital. He favoured a change from the present system prevailing in the hospitals of the province Now they were appointed all at once at a stated time for a year's service. An eighteen months' service would be better—appointments to take place every six months "Dry Labours" was the title of an able paper contributed by Dr Adam H. Wright, Professor of Obstetrics in the Medical Faculty of Toronto University Dr Wright described his method of dealing with these cases and recorded observations on 22 cases. Two lantern demonstrations concluded the evening's programme. The first was conducted by H A. McCallum of London and was on Functional and Organic Diseases of the Nervous System, and the second was by C A. Hodgetts of Toronto, inspector to the Ontario Board of Health, and was on Anomalous Forms of Small-pox. Both of these demonstrations were highly educating and eminently practical

The morning of Thursday was very largely given up to the presentation of clinical cases This proved a new and interesting feature, an improvement on the addresses in medicine and surgery which were wholly eliminated from this annual meeting The following were some of the cases presented, reported, and discussed Situs Inversus in a Child, Leontiasis Ossea, Scleroderma, Charcot's Disease of the Hip (in a young man aged 30 years), Pseudo Hypertrophic Muscular Paralysis, Muscular Dystrophy, Lateral Sclerosis, Adenoma Sebaceum (in a young woman aged 23 years), showing the little tumours well at the side of the nose and on the cheeks (by Graham Chambers of Toronto), An Unusual case of Varicose Veins, Extensive Necrosis of the Skull, Chronic Hereditary Trophœdema of the Lower Extremities, Fracture of the Pelvis in a Child, with Complete Laceration of the Perineum by the Ramus of the Pubic Bone, Subsequent Repair of the Perineum and Bowels and Recovery, Removal of

Stones from the Common Bile Duct Notes of a Patient whose Abdomen had been opened Eight Times, Three cases of Transplantation of the Ureters into the Rectum for Exstrophy of the Bladder, one in an infant girl one in a boy aged six years, and the other in a lad aged 12 years (by George A. Péters of Toronto), An Unusual Case of Multiple Peripheral Neuritis Urticaria Pigmentosa, Marked Disability Arising from Fracture of the Coccyx, Recovery by Amputation of the Coccyx, Chronic Intestinal Obstruction Cured by Operation Three cases of Pyothorax, and a case of Splenic Leukæmia. After the presentation of these very interesting cases the meeting divided into surgical and medical sections

In the surgical section papers were contributed on the x rays and patients shown as follows The Uses of the X Rays other than Diagnostic, by C R. Dickson of Toronto, The Use of the X Rays in Cancer Lupus, and Hodgkin s Disease, by J E. Hett of Berlin and Results that are being Obtained by the Use of the X Rays by John MacMaster of Toronto Three other papers were also contributed to this section Stricture of the Œsophagus by Beverley Welford of Woodstock, Hydrobromic Ether Notes upon its Use as an Anæsthetic in Adenoid and Tonsil Operations by J Gibb-Wishart of Toronto and The Use of Indiarubber Splints in the Deflected Nasal Septa, by J Price Brown of Toronto

The following papers divided the attention of the audience in the Medical Section Climate and Health Resorts of the South Western States of America, by Dr C. D Parfitt, superintendent of the Free Hospital for Consumptives at Gravenhurst, Some Unusual Cases of Syphilis of the Brain and Lungs by Graham Chambers of Toronto Cerebral Embolism, by John Gillies of Teeswater How Much Ophthalmology should the General Practitioner know with Special Reference to the Discovery of the Cause of Headaches by J T Duncan of Toronto Tabes Dorsalis with Involvement of the Cranial Nerves (with presentation of the patient, a man aged 55 years) by H B. Anderson of Toronto, A Case of Brain Tumour with Interesting Localisation Symptoms (with Specimen), by W B Thistle of Toronto, and a Case of Acute Nephritis, by John Hunter of Toronto

The members adjourned at the close of the morning session to a luncheon provided by the committee of arrangements. Dr Powell presided and on his right was Dr Roswell Park, the eminent American surgeon from Buffalo as a guest of the association To the many toasts there were bright and happy responses particularly from perhaps, the oldest practitioner in the province, Dr Harrison of Selkirk who has been practising over 50 years and still continues to practise. He recalled the Coronation of Her late Majesty Queen Victoria and gave many quaint and interesting reminiscences of practice in Canada 50 years ago. On returning after luncheon to the amphitheatre Dr Roswell Park read a short paper on the Surgery of the Gall bladder particularly describing Finney s method of dealing with the gall bladder similar to that for a diseased appendix Dr Ingersoll Olmsted of Hamilton discussed the paper He had performed this operation three times with distinct success. The reading of the following papers closed the session —Fractures of the Shaft of the Femur by Hadley Williams of London Removal of the Gasserian Ganglion for Trigeminal Neuralgia, with exhibition of patient, by H. A. Bruce of Toronto Cancer of the Breast, by T K. Holmes of Chatham, Technique of the Removal of Tuberculous Cervical Glands by L. W Cookburn of Hamilton Abdominal Neuroses by D Campbell Meyers of Toronto and Remarks upon Some Eye Cases by George H. Burnham of Toronto Dr A. R. Robinson and Dr S. A. Knopf were present from New York the latter delivered a short address The following officers were elected President, J O Mitchell, Enniskillen Vice-President, George A Bingham Toronto Treasurer Andrew R. Gordon, Toronto and General Secretary Harold C. Parsons Toronto.

June 23th

NEW YORK.

(FROM OUR OWN CORRESPONDENT)

Public Baths for New York

AT the present time New York proper with a population of 2,000 000 has one public permanent bath building It is now proposed to construct three more for which the city has appropriated $105 000 These are to be opened in July 1903—that is if the contractors do the work in time The buildings will occupy lots measuring 50 by 100 feet and will be suitably furnished for the class of persons who will frequent them. Of the 14 floating baths which the city maintained last year seven are to be closed for sanitary reasons These baths have been on several occasions suspected of being the means of conveying contagion and were the subject of a report by Mr Tucker to the tenement house committee.

Cholera among American Troops in the Philippines

The news from the Philippines with regard to the spread of cholera has of late been extremely disquieting The disease for a considerable time has been prevalent in and about Manila, but has always been reported as being confined to the natives. Latterly, however the reports have stated that the malady has broken out among the soldiers General Chaffee advised the War Department at Washington recently that the army in the Philippines is seriously affected by cholera. Despatches sent out from Manila on June 21st stated that cholera was spreading in the islands. The total number of deaths up to June 21st were 1197 in Manila and 5098 in the provinces, while later reports say that nearly 100 men of the United States Army have succumbed to the disease. The United States Military Medical Department of the Philippines fully recognises the gravity of the situation and is taking energetic measures to stamp out the disease.

Annual Meeting of the American Medical Association.

The annual meeting of the American Medical Association which took place at Saratoga Springs on June 10th, 11th and 12th was on the whole a success. Dr John Allan Wyeth of New York made an efficient president and delivered a practical address The meeting was the first held under the new scheme of reorganisation, the House of Delegates being in charge of the business not directly medical or scientific, thus relieving the pressure of work on the general sessions. The attendance was not nearly so large as had been expected only about 1500 members being present. It is believed that next year when the Committee on Revision of Code of Ethics has proceeded to work, complete harmony will be established between the New York State Medical Society and the National Medical Association.

Hospitals for Contagious Diseases in New York City

The inadequacy of the facilities for dealing with contagious diseases in New York city has long been recognised and many scandals have occurred during the prevalence of smallpox within the past two years owing to the insufficiency of such means The condition of affairs in this respect in the boroughs is far worse than in New York itself for while the city has a contagious hospital of a kind the boroughs provide no means whatever for dealing with patients who need to be segregated The board of health recently applied for an appropriation of $1,025 000 (£205,000) to initiate the necessary reforms, but the board of aldermen was of opinion that such an amount was excessive and voted $500 000 (£100 000) for the purpose—a sum on the face of it wholly inadequate. Not only is the North Brother Island Contagion Hospital much too small badly built, and in every way ill suited to the requirements of a city of the size of New York but there is a corresponding lack of proper means for the conveyance of patients to the isolation hospital. The president of the board of health referring to the situation says The department is not able to care for all the cases of scarlet fever diphtheria and measles as it should properly do. It is also admitted that the hospital plants in Manhattan and in the borough of the Bronx have for many years been in need of additions and alterations.

Social Purity in the Army

Surgeon General Sternberg reported some time since that the Board of Health of Manila had instituted measures for the control of the spread of venereal diseases by infected women of the town by segregating them in certain parts of the city and by a careful system of medical supervision of prostitutes. Thereupon the President caused an official order to be issued by the Secretary of War directing the attention of officers and enlisted men in the army especially of those serving in the tropics, to the following facts. The only really efficient way in which to control diseases due to immorality is to diminish the vice which is the cause of these diseases. It is the duty of regimental and particularly of company officers to try by precept and example, to point out to the men under their control, and particularly to the younger men, the inevitable misery and disaster which follow upon intemperance and upon moral uncleanliness and vicious living The officers should, of course, remember always that the effect of what they say must largely depend upon the lives which they themselves lead. It is in the highest degree necessary that each officer should be an example to his men in the way of temperate and cleanly living He should point out, using the utmost tact, discretion, and good sense, to the men that venereal disease is almost sure to follow licentious living, that it is never a trivial affair, and that it is criminal folly to believe that sexual indulgence is necessary to health Every effort should be made to promote throughout the army a cleanly and moral tone, in word no less than in deed As a nation we feel keen pride in the valour, discipline, and steadfast endurance of our soldiers, and hand-in hand with these qualities must go the virtues of self-restraint, self-respect, and self control

July 1st.

Obituary.

ALEXANDER E MARSDEN, M D St And, F R C S. Edin

The death of Dr Alexander E. Marsden, chairman of the general committee of the Cancer Hospital, Brompton, London, S.W, took place on Wednesday, July 2nd He was born in 1832 and was the son of William Marsden, the founder of the Royal Free and Cancer Hospitals. In 1854 he entered the army as a staff assistant surgeon, served at the General Hospital, Scutari, for three months with Miss Nightingale, then in the trenches before Sebastopol with the 38th regiment, and later as surgeon to the ambulance corps. He was one of the first to enter the city of Sebastopol. For more than 50 years he worked in the interests of the Royal Free and Cancer Hospitals and greatly contributed to their success, particularly of the latter institution He long occupied the position of consulting surgeon to these institutions and was also one of the trustees and member of the committees of each At the Royal Free Hospital he also occupied the position of curator of the museum and for some time was general medical superintendent. At the Cancer Hospital he likewise acted in this capacity, besides devoting a large amount of his time to the management and general welfare of the charity In 1898 he was elected Master of the Worshipful Company of Cordwainers.

Deaths of Eminent Foreign Medical Men —The deaths of the following eminent foreign medical men are announced —Dr Nawrocki professor of physiology in Warsaw, aged 64 years.—Dr Eduard Schider, a well-known physician of Gastein.—Dr *Bizarelli*, *senator of the* Drôme —Dr Dheilly, formerly professor of medical pathology in the Amiens Medical School.

Medical News.

Society of Apothecaries of London —At the primary examination the following candidates have passed in the subjects indicated —

Part I

Biology—L. W Bradshaw Leeds

Chemistry—F M. Cunningham Royal Free Hospital; C A. Mortlock Brown, University College and C E Pring Royal Free Hospital

Materia Medica and Pharmacy—H. F Briggs, University of Michigan J M. Burke, Cork and Middlesex Hospital, W H A Elliott, Leeds and A. R. McEnnery St. Mary's Hospital.

Part II

Anatomy—H. H. R Bayley Charing Cross Hospital E. H G Duncan, St. Bartholomew's Hospital W H A. Elliott, Leeds W F H Ives, Charing Cross Hospital G B Messenger, Westminster Hospital N H Oliver, Guy's Hospital E. D Richardson, St. Mary's Hospital G Rollason, Birmingham C A. Sampson, Charing Cross Hospital; and I. T Walker, St. Thomas's Hospital

Physiology—H. H R. Bayley, *Charing Cross Hospital*, E H. G. Duncan, St. Bartholomew's Hospital, W H. A Elliott Gamble, Leeds; G. Heathcote, Manchester; W. B. W. F H. Ives, Charing Cross Hospital; H. M [illegible]

beds to be called the 'Matilda
ome beds.—Colonel the Right
rde P C., of Seaforde, Clough
Down who died on Feb. 8th by
to the Stewart Institution for
almerston and £1000 in trust for
nary Downpatrick.—Miss Swasbrook
ter by her will bequeathed £100 to
nd the Ear and Throat Institution.

RDIANS AND VACCINATION —
St. Germans (Cornwall) board of
ly 3rd, a communication was read
rnment Board asking for observa
rom the public vaccinators. The
alluded to in THE LANCET of
, that in consequence of the vacci
required at the workhouse on five
public vaccinators were unable to
ments of the Vaccination Act One
that the vaccination fees for 1901
s this year they already amounted
lered this a sufficient reason for
A long discussion followed and
instructed to inquire of the Local
nother private patients were allowed
ors if they were so disposed, (2)
inators were justified in refusing to
a from patients, and (3) whether
iring revaccination should not be
he surgery instead of the public
r homes.

COLLEGE —The annual report
2 states that at the beginning of
there were 38 pupils at the college
to Bombay Presidency and 10 to
ber of military medical pupils on the
time is 46.—Dr N F Surveyor has
n his research work in pharmacology
Petit Laboratory At first he made
a few experiments with sodium saccharate with a view to determine its maximum dose. He has now commenced a series of metabolism experiments and has also been carrying on some observations on the excretion of urobilin in urine of phthisical and septic cases and also on leucocytosis in diseased conditions with Dr R. Row Dr R. Row is continuing his work of original investigations on typhoid fever in the same laboratory The difficulties arising from want of space for anatomical teachings have been to a certain extent overcome by the erection of a temporary shed for dissection in the College Compound and Government has sanctioned the plans and estimates amounting to Rs.78 671 for new anatomical buildings which are now being erected. The report also states that the donation of H. H the Gaikwar of R. 5000 has been thankfully accepted by Government and as a temporary arrangement in this connexion a lectureship on Diseases of the Ear and Throat has been established for five years.

---

power in the alimentary canal and that if a food escapes from the stomach without being digested it will almost certainly be satisfactorily dealt with in the duodenum, and if not there then in the small intestine So that the mere fact that the stomach has struck work does not constitute a necessity for recourse to artificial pre-digested foods unless the *motor* power of the stomach is also deficient. I mean by this that so long as the stomach can drive its contents into the bowel there will be no restriction of digestion worthy of the name. As a fact in pathological chemistry pepsin is almost never absent from the gastric juice unless hydrochloric acid is also absent. If you can find hydrochloric acid in the stomach pepsin is sure to be there too. Of course you know that the cases in which hydrochloric acid is absent from the stomach are very *few* it is often in excess, in the condition known as hyperchlorhydria, but it is rarely absent or so reduced as to make any necessity for pre-digested foods

4 If one considers next the question of increasing any particular constituent of the diet one may ask is it not beneficial to have recourse to artificial foods for this purpose? Here again, one must admit that we do not know enough about nutrition to say what is the value of enriching the diet in these respects. If you are asked in what direction you want to enrich the diet in a particular case and why if you are honest I feel sure that you will say that you do not know There are some diseases, such as diabetes, in which you want to enrich the diet in fat. The diabetic who makes little use of carbohydrates must find some substitute for them, and that substitute is forthcoming in the shape of fat. With regard to carbohydrates there are very few conditions in which you wish to enrich the diet in that respect. What we want to do quite often is to enrich the diet all round we want to feed the patient up, especially in the case of convalescents In that case the best thing is to increase all the constituents—the proteids, the carbohydrates, and the fats. To accomplish that there is no easier way than to get the
at to drink such a food as milk with

story of the leper who was told to bathe in the ri
the treatment was too simple for him. If you t
drink milk or to take any ordinary food he will
no heed to your advice but if you tell him th
so s patent food which he has some trouble
which he has to pay a good deal then he will
large quantities of it and boast that he is d
that aspect which justifies the introduction o
into practice But all the more on that accou
us to know at least something of the chemic
of those foods and not to delude ourselves i
that we are feeding a patient up and giving
amount of nourishment when we are only de
prejudices.

Now we come to consider the composition of
foods, and to enable you to follow better what
on that point I have put into your hands a rou
tion of most of the patent foods at present in
I do not pretend to say that this classification
or logical it is impossible with illogical
patent foods to get a really logical classif
divided them into five great groups.

ool (see Table IV

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

The Housing of the Working Classes

THE Select Committee of the House of Commons on the repayment of loans by local authorities has issued its report and on the subject of schemes for the housing of the working classes it recommends that the maximum period for the repayment of loans should be extended to 80 years The following two paragraphs appear in the report viz :—

> 60 It has not appeared to the committee to be within the terms of their reference to express an opinion upon the question whether the supply of such houses by private enterprise or benevolence has been checked in any case by municipal competition, either actual or anticipated They consider that the sole question with which they are called upon to deal is whether local authorities are unduly hampered by the periods allowed for repayment of loans for the construction of dwelling houses in cases in which such construction is forced upon them either by the legal necessity for re-housing persons displaced by their demolition works or by the proved inadequacy of the supply of houses for the working classes in their district
>
> 61 The reluctance of ratepayers to allow any part of the cost of works to be thrown upon the rates appears to be particularly strong in the case of housing works which, if open market rents are not enforced, confer special advantages on certain individuals This feeling, so far as it exists with regard to the re-housing of displaced persons, is probably founded upon a misapprehension both as to the moral and sanitary benefits which all existing ratepayers derive from the demolition of unhealthy dwellings and as to the real annual cost which is thrown upon the rates by the actual re housing part of municipal schemes

The Midwives Bill

The passage of the Midwives Bill during the present session of Parliament may now be regarded as absolutely certain No changes of substance were made in it in the House of Lords either in Committee of the whole House or before the Standing Committee and there is no prospect of conflict between the two branches of the Legislature As a matter of form the amendments made in the House of Lords will be presented to the House of Commons for its approval Only one division was taken during the Committee stage in the House of Lords and that was upon the section providing a penalty for women who after 1910 habitually and for gain attend confinements without being certified under the Act The Lord Chancellor raised the old question of the friendly neighbour in the rural parishes and spoke in very much the same sense as Mr Jesse Collings did in the House of Commons Though the Duke of Devonshire, President of the Privy Council, made no speech he voted with the Lord Chancellor in the lobby against the section The position of the General Medical Council with regard to the approval of the rules framed by the Central Midwives Board has not been substantially altered As Clause 3 now stands the rules will be valid only if approved by the Privy Council, and the Privy Council before approving them must take into consideration any representations made by the General Medical Council. The words saying that the rules must be submitted to the General Medical Council have disappeared from the clause but it is obvious that the Council must have the rules before it if it is to make any representations with regard to them

Long Hours in the Fruit preserving Trade

This subject was discussed in the House of Lords on Tuesday, July 8th It was introduced by Earl BEAUCHAMP who contended that if jam makers used thoroughly fresh and sound fruit and took proper precautions for its handling they would not require to keep their employés at work for excessive hours For the Home Office Lord Belper explained that new regulations for this trade have been issued under the Factory and Workshops Act of 1901 and he asked for them a fair trial

HOUSE OF COMMONS

WEDNESDAY, JULY 2ND

Hospital Provision for Belfast

Mr WOOD asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been drawn to the application by the Belfast corporation for a loan for the erection of a small pox hospital at Purdysburn, county Down and whether having regard to the practice in England, an inquiry would be held at which the ratepayers would be heard and the rules of the Local Government Board in England as to the striking distance of small pox contagion be adopted —Mr WYNDHAM replied: No application has been received for a loan for the erection of a small pox hospital at Purdysburn consequently no inquiry will be held in the matter In February last an inquiry was held in respect of an application by the Belfast corporation for a loan of £50 000 for the erection of a permanent infectious diseases hospital on the lands of Purdysburn acquired by the corporation for hospital purposes At the inquiry all persons interested had an opportunity of being heard and no objections to the proposal were made This loan was sanctioned in May The question of providing a temporary small pox hospital was not raised when the inquiry into the application for the loan was held

Plague at Hong Kong

Mr WEIR asked the Secretary of State for the Colonies in view of the prevalence of plague at Hong Kong would he consider the expediency of calling for a report as to whether it was practicable to remove some of the slum property in the Chinese quarter of the city with a view to secure improved drainage and sufficient ventilation; and seeing that besides 10,000 foreigners, the city contains upwards of 280,000 Chinese, the majority of whom were located in insanitary dwellings would he consider the advisability of increasing the sanitary staff at the disposal of the Government —Mr CHAMBERLAIN replied I must await the full reports of the medical and sanitary experts Professor Simpson and Mr Osbert Chadwick, who have specially visited Hong Kong in connexion with the plague —Mr WEIR asked when the reports were likely to be forthcoming —Mr CHAMBERLAIN replied: I cannot give any limit for an inquiry of this kind I hope the experts will take all the time they consider necessary

THURSDAY, JULY 3RD

Veterinary Surgeons and the War Office

Captain NORTON asked the Secretary of State for War whether it had been brought to his notice that the Council of the Royal College of Veterinary Surgeons had determined that unless certain concessions were made in the new warrant for the Army Veterinary Department to advise their graduates not to enter the army —Mr BRODRICK replied that he had received a letter to this effect from the Royal College and the President had been informed that the questions involved were under consideration but he could not promise that the concessions demanded could all be made —Captain NORTON said that the principal grievance was the question of army rank and asked whether that would be carefully considered —Mr BRODRICK replied that consideration had been given to this question before, but it had not been found practicable to give the concession desired

MONDAY, JULY 7TH

Scottish Poor-law Medical Officers

Mr CATHCART WASON asked the Lord Advocate if his attention had been directed to the fact that in the highlands and islands of Scotland Poor law medical officers had repeatedly brought under the attention of the Government the circumstances of their position as compared with medical officers holding similar appointments in England and Ireland and if the Government would propose any legislation to improve their position —The LORD ADVOCATE replied: The Secretary for Scotland is not at present prepared to legislate in the direction suggested by the honourable Member

Drink for Habitual Drunkards in Ireland.

Mr M'GOVERN asked the Chief Secretary to the Lord Lieutenant of Ireland whether having regard to the fact that licensed persons who supplied habitual drunkards with drink were rarely prosecuted in Ireland, would he direct the attention of the Royal Irish Constabulary to the Licensing Act with a view to the provisions being put into operation?—Mr WYNDHAM replied: During the past year 215 persons were prosecuted throughout Ireland for breaches of the law in this respect Of these 139 were convicted The attention of the constabulary is about to be directed specially in the matter

TUESDAY, JULY 8TH

Army Medical Establishments Vote

Sir JOHN BATTY TUKE asked the First Lord of the Treasury when he proposed to give the House an opportunity of discussing the vote for medical establishments in the army —Mr BALFOUR replied that when War Office votes were taken the vote for the salary of the Secretary of State for War must be taken first and he was afraid that he could give no promise of a special date for the vote for medical establishments

Ear Troubles in the Hanwell Schools

Sir WALTER FOSTER asked the President of the Local Government Board whether his attention had been called to a medical report issued in February, 1902, in which it was shown that 520 out of 1000 children in the barrack schools of Hanwell could not pass the whisper test for hearing that 335 were or had been the subjects of discharge from one or both ears that 88 of them were suffering from chronic suppuration, and that 434 children out of the 1000 examined had adenoids and what steps had been taken to improve the condition of these children —Mr WALTER LONG replied: I have seen the report referred to from which it appears that the results of the examination of 1000 children at the Hanwell schools were as stated in the question The examination was made by Mr Cheatle by request of the managers of the schools I am informed that the children suffering from adenoids are now receiving surgical treatment and that a committee of the managers, after consultation with Mr Cheatle, are considering the best means of dealing with cases of diseases of the ears It may be mentioned that a similar examination which was made by Dr Willcocks in 1898 revealed a large proportion of adenoid disease As a result of that investigation 107 children from the schools were successfully treated for adenoids at St Bartholomew s Hospital between October 1898, and January 1901 In his report Dr Willcocks stated that the school life and the surroundings of the children could not be held responsible in any sense for adenoid troubles the disease being prevalent among children in all classes of society A similar opinion has been expressed by Mr Cheatle and other medical men interested in the matter

MIDWIVES BILL

DEBATES IN THE HOUSE OF LORDS

FULL REPORT

The Committee stage of the Midwives Bill was taken in the House of Lords on Friday July 4th

The Duke of NORTHUMBERLAND moved to strike out Sections 1 and 2 of Clause 1—namely (1) From and after the first day of January 1910 no woman shall habitually and for gain attend women in childbirth or shall, after the first day of January, 1905 be entitled to take or use the name or title of midwife (either alone or in combination with any other word or words) or any name, title, addition, or description implying that she is certified under this Act, or is a person specially qualified to practise midwifery or is recognised by law as a midwife, unless she be certified under this Act (2) Any woman who after the first day of January, 1905 not being certified under this Act, shall take or use the name of midwife or any other such name title, addition, or description as aforesaid shall be liable on summary conviction to a fine not exceeding £5 and to insert in their places the following sections—viz : "(1) From and after the first day of January, 1905, any woman who not being certified under this Act shall take or use the name or title of midwife (either alone or in combination with any other word or words) or any name, title addition or description implying that she is certified under this Act or is a person specially qualified to practise midwifery or is recognised by law as a midwife shall be liable on summary conviction to a fine not exceeding £5; (2) from and after the first day of January 1910, no woman shall habitually and for gain attend women in childbirth unless she be certified under this Act; any woman so acting without being certified under this Act shall be liable on summary conviction to a fine not exceeding £10, provided this section shall not apply to legally qualified medical practitioners or to anyone called in to render assistance in a case of emergency

The Earl of Portsmouth said that he did not know much about the general merits of the Bill but he thought the particular provision inserted in the House of Commons late in the proceedings there very objectionable. The fact was that in a great many country districts it would be impossible for poor people to get the assistance of what might be called a trained nurse. In some parishes no doubt the proprietors subscribed for the services of one, but that was not the case in all parishes and he was afraid that great hardship would be inflicted if the Bill were passed in its present shape. He could not help thinking that the words to which he took exception were inserted not for the benefit of the working-classes but simply for the benefit of the country doctors. The practice of the country doctor was not a very lucrative one at any time and no doubt much of it consisted in attending the confinements of poor people He did not know that the country doctor was always particularly expert and efficacious but he did know that in many cases poor people preferred the assistance of a midwife to that of the doctor and he thought it would be very hard if they were obliged to go to the latter Altogether he thought this new provision a mistake and, indeed altogether beyond the purpose of this legislation. He would ask, too, whether it was proposed to put the charge for a trained nurse upon the rates If it was not proposed then there must be many parishes without a trained nurse. He hoped their lordships would see their way to strike out the words which seemed to him mischievous and exceedingly vexatious

Lord Clonbrook said that in Ireland there was a trained nurse in connexion with each dispensary district and he did not see why the same state of things should not exist in England

The Lord Chancellor said that if there was in England the same system as in Ireland he should have no objection to this provision but unfortunately there was no such system Indeed, if they had the Irish system in England he imagined that the need for this legislation would be got rid of altogether The question their lordships had to deal with was after all very much a question of fact—whether or not in the rural districts of England this provision would affect many of the poorer classes in a very harsh manner and cause a great deal of suffering The evidence which had been put before him went to show that it would and that the mischief would go on increasing It appeared to him that the matter had not been sufficiently investigated in order to ascertain the effect of the provision. He should have thought that a great many of their lordships themselves would know what was the condition of rural life in England He rather thought that the noble duke himself (the Duke of Northumberland) must have some knowledge upon the subject, and he should have deferred very much to his knowledge and experience This was a matter which had not been properly threshed out in the other House. As the Bill was originally framed it said that no one should assume the name and character of a midwife who had not got a certificate. No one would object to that. It passed through the Grand Committee and still was without this compulsory clause. Then at the last moment this clause was inserted penalising a whole class of persons without the least inquiry This alteration changed the whole character of the Bill and it seemed to him therefore that it was a matter which should be considered Could anybody suppose that there would be a rush for education and qualification on the part of midwives without any further inducement than was offered by this Bill? He thought that the whole question should be inquired into It was said that the provision would not come into operation for eight years In that event there would be no suffering through inquiry It could not be said that it was an urgent question if they were to wait eight years for the operation of the provision Before committing themselves he thought their lordships would do well to have the facts of the case clearly ascertained

The Duke of Northumberland said that there were one or two fallacies which he should like to point out Over and over again the expression trained nurse" had been used It was not proposed to insist upon a midwife being a trained nurse." The expression "trained nurse" included a very much more complete education than was contemplated under this Bill There was no question of any charge upon the rates As for the provision to which so much exception had been taken, he must confess that the more he considered it the more was he convinced of its being essential for the proper working of the Bill. They had been asked what did they know about the necessity for such legislation? That was an argument against the whole Bill. This Bill was no new thing; it had been brought on year after year It was held by those who supported it that there was a great necessity for it, that there was a great deal of harm done in the country by untrained midwives and if that were to be stopped there must be a penalty of some kind The penalty proposed was only for the women who habitually and for gain attended women in childbirth—that was to say did something for which she was not certified Whether there was any hardship in rural districts would depend entirely upon the rules laid down by the Privy Council He quite admitted that they were placing in the hands of the Privy Council very large responsibilities. It would be for the Privy Council to decide the rules and regulations under which women would be certified to act as midwives Though he was afraid he could not assure the Lord Chancellor that his experience in these matters was very profound yet he thought most of their lordships with experience of the rural districts did not see any cause to apprehend any serious difficulty in obtaining the services of midwives who would be certified under this Act He saw an enormous difficulty in rural districts in always obtaining the services of a certified midwife but then that had been carefully guarded in the Bill. There must be many cases in which the neighbour came in not without receiving remuneration and there was nothing in the Bill to prevent the neighbour coming in and giving that assistance which was of so much value. In all the circumstances he could not believe that any real hardship would be caused by the Bill Another point to bear in mind was that all the existing midwives who gave evidence of respectability and of *bona fide* practice would be certified as matter of course. All that was proposed was at the end of eight years any woman who wished to enter the profession should qualify herself by proper training

Earl Spencer said that he did not quite understand his noble friend (Lord Portsmouth) as to whether he meant to move the omission of the words to which he had called attention Nor did he quite understand what the Lord Chancellor intended to do; his lordship spoke, as it seemed to him against the whole clause. As far as he (Lord Spencer) could see this clause contained almost the pith and essence of the Bill and if it were omitted it would be better to leave the Bill alone altogether He had had some very considerable doubt about the policy of this Bill and he had made it his business to study the question with some care and he differed entirely from the Lord Chancellor in his view as to their having been no inquiry There was a full report by a Committee of the House of Commons showing that there had been most exhaustive inquiry while the Bill itself appeared to belong to the class of measures known as hardy annuals. It was only after 12 years or more of constant work that the Bill had been brought to a pitch which had enabled it to pass in the other House If the Bill prevented women in small villages from calling in their neighbour who might have great experience in the birth of children it would no doubt be a very hard thing but it did nothing of the sort. All the Bill did was to prevent a woman who gave this aid from advertising herself as a midwife From the evidence he found that there were in England and Wales 4500 women who perished annually in childbirth or one woman to every 200 confinements. In the hospitals where there were trained nurses the mortality was only one in 600 That meant that if outside these hospitals there were the same trained assistance as inside there would be a saving of 3000 lives per annum. Surely that was a matter that ought to be weighed and considered and dealt with by the Legislature; it had convinced him of the absolute necessity of dealing with the evil in some way

The Lord Chancellor said that he had not said one word against the superiority of trained nurses or about the absence of medical attendance. He had not the smallest doubt that it would be very much better if every poor woman were attended by a trained surgeon His point was, Were they quite sure that in their effort to do what he believed a very good thing they might not be doing more harm than good and that by preventing what the poor had they might prevent them from having anything at all? He repeated that this provision had been inserted at the last moment. The noble lord had spoken of the Bill as a hardy annual, but did he suggest that this penal clause had ever before been in the Bill?

The Earl of Cork said that anyone who had lived in the country and knew how children were brought into the world knew that very often mothers had to depend entirely upon the help of their neighbours, and he believed that on the whole the children were brought into the world in a good and healthy condition. He insisted that the clause in its present shape would deter neighbours from giving assistance.

Lord Balfour of Burleigh said that in his opinion much of the discussion that had taken place was beside the point. The question their lordships had to decide was whether this was a wise and satisfactory provision to have in the Bill If he were to go into the history of the matter he could point out that the provision was not a new one before Parliament. It was in the Bill of 1900 What was proposed was that a woman should not habitually and for gain attend women in childbirth without being certified the operation of the provision being postponed for a period of eight years Now there could be no doubt that in this sort of legislation they must take care of anything which by any stretch of language could be called a vested interest. If a woman was now actually and in good faith in the prosecution of this profession then he thought it would be unfair arbitrarily to come down and interfere with her Under the Bill she was entitled to be recognised provided she was of good character On the other hand it must be admitted that there was a great evil in connexion with this matter and that many of those who called themselves midwives were utterly regardless of the lives of those whom they attended It had been proved over and over again at coroners inquests that those who called themselves midwives and habitually and for gain took up the profession did not sufficiently regard their responsibilities and it was necessary that some sort of check should be put upon them What was hoped was that by this form of training there would be greater skill which was obviously desirable, and at the same time by postponing the condition for eight years there would be no hardship to those who were likely to enter the calling in the future He would not go so far as to say that if this sub-section were omitted the whole value of the Bill would be lost; he believed that it would still be a very valuable Bill, but he believed that it would be a less valuable Bill than as it stood at present and for this reason It was all very well to say that a woman who was a midwife should be trained but unless there was some practical supervision some handicap upon those who were not trained there would be no great zeal in taking the certificate and proving competence for the work He did not believe that the provision would cause any real hardship and he hoped their lordships would accept it.

The Earl of Portsmouth said that he felt the provision had been inserted to further professional interests. It savoured too much of grandmotherly interference with the working classes which he was sure was not acceptable to them

The two sections standing in the Bill were then struck out and the first section proposed by the Duke of Northumberland was inserted without a division

The Duke of Northumberland then formally moved the insertion of the second section he had proposed

Lord Tweedmouth said that if Parliament made this declaration in favour of certification and did not provide a penalty the whole thing would be a farce. There must be a provision for enforcing the views of Parliament.

A division was then taken when the new section was adopted by 66 votes against 19

The peers who voted against the section were the Lord Chancellor the Duke of Devonshire Earl Carrington, the Earl of Morley the Earl of Portsmouth, Viscount Sidmouth Lord Belper the Earl of Cork, Lord Colchester, Lord Hatherton Lord Hawkesbury, Lord Heneage, Lord Howard of Glossop Lord Lamington Lord Leigh Lord Monkswell Lord Mowbray Lord Thring and Lord Wimborne

Among the 66 peers who voted for the section were the Duke of

Grafton the Duke of Northumberland, the Duke of Portland, the Duke of Rutland the Marquis of Lansdowne the Marquis of Ripon, the Earl of Camperdown the Earl of Derby, the Earl of Jersey, Earl Spencer, the Marquis of Londonderry, Viscount Cross Viscount Knutsford Viscount Llandaff the Bishop of Winchester Lord Balfour of Burleigh, Lord James of Hereford, Lord Reay, the Earl of Rosebery Lord Sandhurst Lord Tweedmouth, and Lord Welby

Lord THRING moved to strike out of Section 5 the reference to the undertaking of cases of abnormality or disease in connexion with parturition and to insert the following as a separate section, viz :—

"It shall be the duty of a midwife not to undertake without the assistance of a registered medical practitioner any case which she knows or might with reasonable care have known, to be one of abnormality or disease in connexion with parturition if she does so she shall be liable to a penalty not exceeding £5 unless she proves to the court that she was unable to procure the attendance of a registered medical practitioner"

The Duke of DEVONSHIRE said that the words to which exception was taken by the noble Lord were inserted at the instance of the Privy Council in order to meet the views of the General Medical Council and he hoped they would be retained in the Bill

Lord THRING thought the clause most unjust and that it would make the places of these women almost untenable if it were enforced

The amendment was negatived without a division

On the motion of the Duke of NORTHUMBERLAND words were inserted in Clause 3 giving a seat on the Central Midwives Board to a representative of the Queen Victoria s Jubilee Institute for Nurses

Lord WELBY moved an amendment to subject the Central Midwives Board in matters of expenditure to the previous approval of the Privy Council

The Duke of DEVONSHIRE resisted the amendment saying that it was unnecessary and that the Privy Council could not efficiently undertake the proposed responsibility

The amendment was negatived without a division

Consideration was then given to the provision in Clause 3 that "Rules framed under this section shall be valid only if approved by the Privy Council and the Privy Council before approving any such rules shall submit them to the General Medical Council and shall take into consideration any representations which that Council may make with respect thereto"

Lord THRING moved to strike out everything after the first "the Privy Council" saying that it was unprecedented to give such an order as this to the Privy Council

Lord BALFOUR of BURLEIGH said that the General Medical Council had been anxious for more control and he could see no harm in allowing the Privy Council to take the opinion of the General Medical Council. All that was provided for was that the Privy Council before approving the rules should submit them to the General Medical Council and take into consideration any representations it might make, but there was nothing in the clause binding the Privy Council to adopt the views of the General Medical Council He thought the General Medical Council had sufficient knowledge and experience to entitle it to know what was being done by the Government department before that department made its rules effective He felt sure that the clause did not ask the Privy Council to do more than it would do in any circumstances

Earl RUSSELL said that he quite agreed that this was what the Privy Council would probably do in any case but the provision in the Bill was mandatory and that was quite a different matter

Lord THRING said that while he did not propose to press his amendment to a division he still thought this a very extraordinary provision to find in an Act of Parliament

The Earl of CAMPERDOWN took the view that it was not giving the Privy Council the position to which it was entitled to order it to submit the rules to the General Medical Council He felt confident that the Privy Council would never think of issuing the rules without being assured that they were in conformity with what was right and that with that object it would consult the General Medical Council The words in the clause however, suggested that the General Medical Council had too much power in connexion with the Bill and he was sure their presence there would not increase the popularity of the legislation throughout the country

Lord BALFOUR of BURLEIGH said that as there appeared to be strong objection to the words as they stood he would suggest that the words 'shall submit them to the General Medical Council be struck out so that the Privy Council should only be required to take into consideration any representations which that body might make

The Earl of CAMPERDOWN thought that would not help matters much because if the Privy Council were to take into consideration any representations of the General Medical Council that would imply that the rules should be submitted to the latter body

The suggestion of Lord Balfour of Burleigh was adopted on the understanding that the matter would be subject to revision when the Bill was considered in the Standing Committee

The Earl of MAYO moved to insert at the end of the clause these words viz — Provided always that any woman holding a certificate in midwifery from the Hospital for the Relief of Poor Lying in Women in Dublin (commonly known as the *Rotunda* Hospital') shall, upon production of such certificate be admitted to the roll of midwives without any further course of training or examination and shall be entitled to be certified under this Act

The Duke of NORTHUMBERLAND opposing the amendment said that the great duty of the Central Midwives Board would be to see that only properly qualified women were admitted and he could not help thinking that it would be invidious to name any particular institution in the manner proposed

The amendment was not pressed

On Clause 4 dealing with fees and expenses,

The Marquis of RIPON protested against the proposed apportionment among county and county borough councils of any deficiency that might occur in the balance of the accounts of the Central Midwives Board It was bad in principle, he said, and he could not give it his approval

On the motion of the Duke of NORTHUMBERLAND Clause 5 was made to read: There shall be a *roll of midwives* containing (1) the names of those midwives who have been certified under Clause 2 of this Act (2) the names of all other midwives who have been certified under this Act

On the motion of Lord WELBY words were inserted in Clause 6 requiring the approval of the Privy Council for the appointment certain of the officers of the Central Midwives Board

In Clause 8 dealing with the local supervision of midwives it said that it shall be the duty of the local supervising authority suspend any midwife from practice in accordance with the rules und the Act, if such suspension appears necessary, and on the motion of t Duke of NORTHUMBERLAND it was agreed to add "in order to prev the spread of infection'

Also on the motion of his lordship it was agreed to insert in Clause these words—viz "Any woman thinking herself aggrieved by a decision of the Midwives Board, removing her name from the roll midwives, may appeal therefrom to the High Court of Justice with three months after the *notification of such decision to her* but further appeal shall be allowed

This concluded the consideration of the Bill by Committee of whole House

On Tuesday, July 8th, the Bill was considered by the Stand Committee of the House of Lords

On the motion of the Duke of NORTHUMBERLAND it was agreed alter the date in the first section of Clause 1 to April 1st, 1905, and the second section to April 1st 1910

The Bishop of HEREFORD moved that the second section which p vides a penalty for uncertified practice come into force on April 1905 His Lordship pointed out that Clause 2 enabled women now practice to get certification on production of evidence of good charac Presumably, therefore every respectable woman would apply to certified, and women who were not respectable would be free to go practising until April 1st, 1910 without any restriction

The Duke of NORTHUMBERLAND said that he was afraid that he co not accept the amendment It was really a case of endeavouring to meet divergent views and the provision in the clause represented a compromise to which he must adhere By deferring the operation of the section for eight years the Central Midwives Board and the Privy Council would be able to see how the Act generally worked and to modify their rules in the light of experience or even to propose amending legislation

Lord BELPER said that he was instructed by the Home Office to oppose the amendment, the view of that department being that it would be well to have this interval of time before the penal provision came into force.

The amendment was rejected without a division

On the motion of the Duke of NORTHUMBERLAND words were inserted in Clause 3 making certain members of the Central Midwives Board eligible for reappointment

The words introduced in Committee of the whole House in Clause 14 giving an appeal from the General Midwives Board to the High Court of Justice were struck out of that clause and made a separate clause When the Earl of CORK suggested that a midwife in some distant part of the country was not likely to be able to afford the cost of an appeal to the High Court the Duke of NORTHUMBERLAND explained to his lordship that the provision had been introduced at the instance of Lord Lindley and said that it could not possibly do any harm

On the motion of Lord WELBY Clause 6 was made to read that the Central Midwives Board shall, with the *previous sanction* of the Privy Council, appoint a secretary and such other officers as may be required and every person so appointed shall be paid such salary as the Privy Council may approve and shall be removeable at the pleasure of the Board

Lord BELPER moved the omission of Clause 7 which said that "Where a person whose name is entered on the roll of midwives has, either before or after the passing of this Act, and either before or after her name is so entered on the roll, been convicted either in His Majesty s dominions or elsewhere of an offence which, if committed in England would be a felony or misdemeanour or been guilty of any disgraceful conduct in her practice as a midwife that person shall be liable to have her name erased from the roll The Midwives Board shall cause inquiry to be made into the case of a person alleged to be liable to have her name erased under this section and on proof of such conviction or of such disgraceful conduct shall cause the name of such person to be erased from the roll' His lordship described the clause as most objectionable and absolutely unnecessary, having regard to the disciplinary powers of the Board in Clause 3

The Duke of NORTHUMBERLAND said that this was an agreed clause in the House of Commons and he understood that the Government made no objection to its insertion in that House If it were struck out now he hoped that the Government would see that the Bill did not suffer in consequence when it was returned to the House of Commons without it

The clause was struck out of the Bill

Some discussion took place as to the character of the notice of the Act to be given by county councils to midwives but no change was made in the Bill it being understood that Lord Belper would bring up a new set of words on the report stage

This completed the consideration of the Bill which was ordered to be reported to the House

Notes, Short Comments, and Answers to Correspondents.

A PLEA FOR THE FINAL YEAR STUDENT

To the Editors of The Lancet

Sirs,—It was with a feeling of disappointment that I read th criticisms on my former letter by Dr N F Stallard I had hope that if an adverse expression of opinion were necessary som senior member of our profession would have given it, but thi maintained silence leads me to believe, possibly with presumptio that part if not the whole, of my letter has found favour in thei eyes With your kind permission I shall endeavour to reply t those criticisms As regards pharmacy I still adhere to my opinio that two hours work in that subject could make a student average ability prescribe with facility any necessary drug as the a of combining medicines belongs more to materia medica tha to pharmacy and a knowledge of their properties must be acquire prior to their use If, as Dr Stallard asserts, we would be at t mercy of the dispensing chemist, I fail to see any humility appealing to the judgment of men who are, and have to be, bett versed in the art of pharmacy and materia medica than the avera medical man, and in this country more attention is, as a rule, paid prescribing what will relieve and cure a patient than to elegance writing prescriptions, which latter accomplishment involves very slig brain exertion on the part of the writer His argument and cor parisons as to biology and pathology constituting the A B C of o professional training are really too absurd, as pathology, which rendered compulsory in the final of most curricula, could hardly that reason lay claim to a position in the medical alphabet, and t too numerous divergent opinions arising from its subject matter mu always prohibit it from being standardised In the same way biolog which only within the past few years has become a part of t curriculum, and did not enter into the studies of most of our present d teachers, cannot, with justice, lay claim to being part of the car foundation of a science which has been known and practised centuries In my opinion anatomy should rightly be called the alpha of the profession I admit that I have indeed heard of the seru treatment of diphtheria but, personally, I have little faith in it, as one hears of pneumonia, pertussis, and follicular tonsillitis, &c., bei diagnosed and treated with the now familiar ' needle in the back' a serum injection, and with, needless to observe, brilliant results, o can hardly wonder at the astonishing numerous statistics adduced its favour For the benefit of Dr Stallard's future experience let say that real genuine diphtheria is a comparatively rare disease, and in my opinion fatal in children of tender years after puberty the anatomical changes in the throat render a more favourable prognosis for the sufferer The recognition of the bacillus of tuberculosis in a phthisical patient is, to my mind, of practically no importance for the following reasons—viz., the bacillus can do no harm unless the host has an hereditary predisposition to the disease and, also, once phthisis has developed under the same conditions, very little except of a palliative nature can be done for the patient It has yet to be proved to my satisfaction that phthisis is curable and that the bacillus is the direct cause of the disease, which some pathologists imagine it to be As regards sending a consumptive to a sanatorium fully as much benefit, in my opinion, can be derived from sending him or her to the seaside, or on a long sea voyage, as it is a well known fact that phthisical subjects under those conditions regain a certain amount of health and may live for a score of years and that being so, why make a speciality of the "open air treatment' ? I venture to predict that after a few years busy practice Dr Stallard will considerably modify his views on certain points and begin to think that, after all, certain diseases are not, in practice, so formidable as they are depicted in theory, and if he views and treats his cases more from a clinical than from a microbic standpoint he will have better results in his practice With reference to the use of antiseptics I may add, *en passant*, that I would use them under no conditions as they are entirely unnecessary where there is an abundance of clean water and soap present Apologising for this lengthy letter

I am Sirs yours faithfully
R H D Popf, L R C S Irel

Belfast, June 16th, 1902.

THE HOLIDAYS OF IRISH POOR LAW MEDICAL OFFICERS

To the Editors of The Lancet

Sirs —I see in your issue of June 28th, p 1868, a notice of the correspondence &c., which I forwarded to you relative to my difficulty in obtaining annual leave from the Abbeyleix board of guardians and the Local Government Board, which I beg leave to thank you for having inserted in your journal At the same time I must draw your attention to some points on which you appear to be under misapprehension First, the heading under which your notice appears is misleading So far from being merely a personal or trivial matter it is one which seriously affects the majority of Irish dispensary medical officers at present and it is only by giving publicity to the grievances under which they suffer individual cases that they can hope for universal redress Your statement at there appears to have been some informality on my part in aking my application for leave is quite inaccurate. If you refer to the orrespondence and copy of minutes of the Abbeyleix board you will see at I carefully fulfilled every condition of the dispensary rules and at my application came before the board in due course. It would also em from your article in THE LANCET that the Abbeyleix board had me just grounds of "displeasure against me. Their sole reason for fusing my leave was that some time previously they having refused pay me my fees under the Labourers Inquiry Act, I was obliged to ecover same from them in the county court, which the verdict proved was legally entitled to

I am Sirs yours faithfully

July 3rd 1902. R. H D OLIER DUCKWORTH

THE Y" FUND

URGEON-GENERAL H S MUIR begs thankfully to acknowledge additional donations towards the above Fund from Mrs. Fardon (and friends) Mr Edgar Stevenson (who sends a donation from Anon") Civilian Surgeons S Forslike and J A. Howard and the following officers of the Royal Army Medical Corps: Colonel W L. Gubbins Lieutenant-Colonels F W Trevor J C. Dorman C.M.G G H Sylvester W J Macnamara, A. G Kay and T P Woodhouse Majors C H. Melville, J W Bullen R I Power F S Le Quesne V C. C H Hale D.S O., W T Swan W Dowman A. A. Sutton D.S O M. P Holt M W H. Russell, H. C. Thurston C.M G B Davis M Kelly J M. F Shine T Daly J G Black, C R. A. Julian C.M.G., W Turner D Stiell, and A. Y Reilly; Captains C A Stone, S. F St. D Green H S Thurston C J O'Gorman D S O., J R. McMunn E. H Condon G S Crawford G H. F Stammers, W W O Beveridge, H. C. Anderson D S O C W H Whitestone, B Forde, N Tyacke and H M Morphew; Lieutenants G M. Goldsmith, B R Dinnis, H H Norman, A. J W Wells S Adye-Curran, J A. Hartigan and A. W A. Irwin; and the officers with the columns under Colonel Little and Colonel Fanshawe. The fund now amounts to £416. It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly "handing on" to *confrères*). Should any reader of THE LANCET desire further particulars with a view to expressing *practical sympathy* a copy of the letter will be forwarded on application to Surgeon-General Muir 28, Kensington gardens-terrace, Hyde Park London, W

A POINT IN ETHICS

To the Editors of THE LANCET

SIRS —May I ask what is usual in the following case? I attended a idwifery case for a fellow practitioner on an emergency I had to drive ve miles out into the country and was away from home four hours hould I act in accordance with custom if I accepted a whole or part of he fee from the practitioner whose case it was, or is it usual for one edical man to act for another in such a case without fee at all?

I am Sirs yours faithfully

July 4th 1902. M D

*** The fairest course in such a case is to divide the fee —ED L.

HOLIDAY COURSES IN BERLIN

J S L. will feel obliged for information as to the holiday courses for medical studies in Berlin.

THREAD WORMS AND APPENDICITIS

To the Editors of THE LANCET

SIRS,—In THE LANCET of July 5th p. 58, a correspondent who signs imself Harlesden asks whether appendicitis in a child is likely to e caused by thread-worms and whether the case to which he refers n which the association was observed is unusual I venture to refer our correspondent to an article in the *British Medical Journal* of pril 15th 1899 in which the presence of thread-worms in the vermi orm appendix was shown to be a frequent occurrence in children In ne case recorded there 111 thread worms were found in the appendix hich was swollen and thickened. In this particular case the boy aged ine years, had complained of pain in the right iliac fossa which had iven rise to suspicion of appendicitis That a catarrhal condition of he appendix may occur from such a cause was clear from the series f observations there recorded the appendix was found to be swollen nd thickened in several cases. Indeed it was sometimes possible o predict the presence of thread worms in the appendix before pening it from its swollen appearance" Obviously if the vermiform ppendix is a common habitat of the thread worm—out of 38 cases n which the oxyuris vermicularis was present in children the worm was found in the appendix in no less than 25—the presence of thread orms in that situation in any case of appendicitis may be a ere coincidence, but the frequency of swelling of the wall of the ppendix when the worms are there suggests, at least that a more cute inflammation may result in some cases. Whether the presence f thread worms is in itself sufficient to cause such inflammation s a difficult point to determine but it hardly affects the question of tiological significance for there can be little doubt that any irritation which produces such a catarrhal condition of the appendix as was resent in these cases will almost certainly diminish the resistance of the wall of the appendix to invasion by micro-organisms and so redispose to a more extensive ute inflammation. Since this paper was published at least one case of appendicitis associated with thread worms in the appendix has been recorded A boy aged about eight years underwent operation for catarrhal appendicitis at the Presbyterian Hospital in New York and section of the organ showed several specimens of oxyuris in the lumen (Pediatrics May 15th 1900, p 411) The very similar case mentioned by your correspondent is of considerable interest in relation to the observa tions mentioned above. I have used the term appendicitis" here advisedly as apart from its ugly hybridism it is evidently more accurate for these particular cases than the word perityphlitis."

I am Sirs yours faithfully

July 5th 1902. GEORGE F STILL.

To the Editors of THE LANCET

SIRS —It may interest your correspondent Harlesden" to know that on the 2nd of this month a lad was operated upon here for what appeared to be recurrent slight attacks of appendicitis The appendix was rem ved although it appeared to be normal but on cutting into it afterwards a live thread worm was found at its apex

I am Sirs, yours faithfully

The Infirmary Leicester July 5th 1902. F BOLTON CARTER.

*** We refer our correspondents to an annotation which appeared in THE LANCET as recently as February of this year (THE LANCET Feb. 22nd, 1902 p 539) entitled Appendicular Colic from Thread worms in the Vermiform Appendix."—ED L.

THE ASSOCIATION OF GERMAN PRACTITIONERS AND NATURALISTS

To the Editors of THE LANCET

SIRS —In answer to the question of your correspondent (W S) in THE LANCET of June 28th p 1863, relative to the Society of German Scientists and Doctors" he will obtain the information he requires by applying to Herrn Primarius Dr Finck, Geschäftsführer der Gesellschaft Deutscher Naturforscher und Aerzte" (für 1902) Karlsbad

I am, Sirs yours faithfully

Tiefenau Zürich, July 2nd 1902. A PAULS

ADVERTISEMENT

THE rules governing medical etiquette are in some ways different in the colonies from what they are in this country Thus in Australia and New Zealand it is the custom for medical men to advertise their names, addresses and the hours at which they may be seen in the public press. This we have no doubt is necessary in a somewhat sparsely inhabited country and in one where patients have to come from great distances There are however limits beyond which advertisement should not go and a pamphlet which we have received to our thinking transcends these limits It is entitled "Testimonials to Dr E G Leger Erson, Physician and Surgeon (Registered in Great Britain and Australasia) ' We cannot find Mr Erson's name in the Medical Register for 1902 but in the Australasian Medical Directory for 1896 we find that he is entered as "L. et L Mid R C.P Edin 1876." From the testimonials, copies of which, we hear are distributed broadcast we presume that Mr Erson is at present—for by internal evidence the pamphlet appeared during last year—surgeon to the Peak Hill Hospital He has 'late' and "formerly" held a number of appointments ranging from that of honorary physician to the Auckland Hospital to that of Vice president of the Manly Bowling Club From his testimonials we also learn that people listen with rapture "to the well rounded quality of his superb tenor voice and the effectiveness of rendition" A superb tenor voice is an enviable possession, but we think that Mr Erson would be well advised not to scatter the pamphlet to which we have referred among either his own or other practitioners patients

THE KING AND THE QUACK

A CORRESPONDENT has sent us a copy of the *Weekly Times and Echo* published on Sunday, July 6th, and has marked an article from the pen of Mr T R Allinson entitled 'How the King might have been Cured without Operation" The article contains such useful pathology as the attributing of perityphlitis to the use of tea, coffee, and tobacco and recommends as treatment warm sponging once or twice a day in a bed in a room with the window open—"no drugs are given and no operation is advised The person we are quoting is of course, well known to the medical profession as one who lives by abusing that profession to which he once belonged In an answer to correspondents on the same page he says: 'If I had seen the King on the Monday by the following Monday he would have been up and about and that without operation The drug doctors know nothing of what nature will do I have cured at least two dozen cases like his without an operation or a drop of medicine We suppose this sort of audacious balderdash results in poor dupes going to see Mr Allinson The newspaper which publishes such rubbish incurs a grave responsibility Unfortunately, the responsibility is only a moral one

WANTED—A HOME

To the Editors of THE LANCET

SIRS,—I should be much obliged if any of your readers could help me in the matter of a phthisical patient. She spent last winter in a sanatorium in the south and was much benefited and I think the prospect of cure is fairly good if she could continue the treatment This she is unable to do for want of funds but would gladly accept a position as nurse or helper in such an institution, either for a very small salary or in return for board and treatment She is a good amateur nurse and has nursed several cases of phthisis (from which, no doubt she contracted the disease) and her condition is at present quite good enough to enable her to do light work She is of a very bright and cheery disposition I should be glad if anyone interested would communicate with me

I am, Sirs yours faithfully

Wylam on Tyne, July 4th, 1902. W H BISHOP

To the Editors of THE LANCET

SIRS —I shall be obliged if someone will kindly inform me through the medium of your Answers to Correspondents" column whether there exists a suitable home for a young lady of small means suffering from hysteria in rather a severe form A place where Weir Mitchell s treatment is in vogue would be preferable

I am, Sirs yours faithfully,

D LL. K PRICHARD M R C S Eng L R C P Lond

The Ferns, Bettws y Coed, N W July 7th, 1902.

THE BACKBONE OF ANTI VACCINATION

IN an annotation upon the Imperial Vaccination League which appeared in our issue of July 5th p 33 we mentioned that most of the detractors of vaccination were men and women of no intellectual calibre Unfortunately persons of this description are just those who gain the ear of the masses In the issue of the *Northern Echo* of June 27th there are two typical advertisements emanating from an anti vaccinationist His name is J Clayton and he lives at Middlesbrough He calls himself a medical herbalist and tumour specialist, but he gives advice and treatment with regard to all complaints During the last nine years he has taken off over 200 tumours without cutting from almost every part of the body—"Cause, Vaccination. Mr Clayton' views on pathology are simple He professes to believe that vaccination causes tumours "because when the tumour comes off you ca see the same number of holes in the part where the tumour come off, oozing with matter that correspond to the same number of mark that are on the arm, so that it leaves no doubt on the subject" Mr Clayton further states that when the calf lymph travels to the live it breeds small pox, when it travels to the throat diphtheria Whe the lymph travels to the brain we have diseases of the mind W are compelled to think from this remark that Mr Clayton ha evidently been vaccinated

INDEPENDENCE DAY AND TOY PISTOLS

THE most universal method of celebrating a joyous occasion is t make a noise The youthful Britisher blows horns and squeakers o howls in the street The youthful American lets off toy pistols Sometimes these inflict wounds and in the year 1900 there were 2 persons who died from tetanus in Chicago from wounds received o Independence Day This set the health authorities thinking and this year the mayor issued a proclamation against the discharge o dynamite, firearms, and cannon crackers, and especially against the sale of toy pistols or metal caps to children The result of this wa that only four persons died from tetanus owing to injuries receive on Independence Day this year Over here the toy pistol is fatal not so much from tetanus as from direct injury Various attempts have been made in Parliament to pass a Pistols Bill which should prevent the sale of these lethal toys but the last Bill brought in wa thrown out mainly, so far as we remember, owing to the opposition o a Radical Member

◆

Sybil —The treatment is rubbish The indecent questions that ar asked have no bearing on the condition The advertisers ar dangerous quacks

Post-Graduate College (West London Hospital, Hammersmith road, W).—5 p.m. Mr Keetley Acute Intestinal Obstruction.

EDITORIAL NOTICES

It is most important that communications relating to the Editorial business of The Lancet should be addressed *exclusively* 'To the Editors, and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures original articles and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed To the Sub-Editor

Letters relating to the publication, sale and advertising departments of The Lancet *should be addressed To the Manager*

We cannot undertake to return MSS. not used

MANAGER'S NOTICES

THE INDEX TO THE LANCET

The Index to Vol. I. of 1902, which was completed with the issue of June 28th and the Title-page to the Volume, were given in The Lancet of July 5th.

VOLUMES AND CASES.

Volumes for the first half of the year 1902 are now ready Bound in cloth gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are now ready Cloth, gilt lettered, price 2*s.* by post 2*s.* 3*d*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of The Lancet at their Offices, 423, Strand, W C , are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach The Lancet Offices, and consequently inquiries concerning missing copies, &c. should be sent to the Agent to whom the subscription is paid and *not* to The Lancet Offices.

Subscribers, by sending their subscriptions direct to The Lancet Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from The Lancet Offices or from Agents, are —

For the United Kingdom		To the Colonies and Abroad	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager Mr Charles Good, The Lancet Offices, 423, Strand, London, W C

Subscribers abroad are particularly requested to note the rates of subscriptions given above. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of The Lancet necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of The Lancet have for many years paid, and continue to pay the whole of the heavy cost of postage on overweight foreign issues , and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—The Manager, The Lancet Offices, 423, Strand London England

Two Lectures

ON

INJURIES OF NERVES

Delivered at St. Bartholomew's Hospital on March 19th and 21st 1902

By ANTHONY A BOWLBY, C M G,
F R C S Eng,
JOINT LECTURER ON SURGERY

LECTURE I.

Delivered on March 19th.

Gentlemen —In commencing a brief description of injuries of nerves and their results I must remind you first of all that the effects of an injury of a nerve are out of all proportion to its size, and that, consequently, although only a very small punctured wound may have been inflicted on a patient's arm yet as a consequence of that the hand or a great part of it may be practically paralysed and useless. Hence it is that injuries of nerves assume a very much greater importance than the size of the wounds which inflict those injuries would give you cause to consider probable. I propose to begin by describing to you briefly what happens in the upper end of a divided nerve. In the first place, it is certain that after a nerve has been cut across the changes which take place in the upper end are primarily limited to that part of the nerve immediately above the point of section and the results of these changes are best seen in the nerves of a stump. When a person has had an amputation performed and you have an opportunity of examining the stump after the lapse of months, or possibly years, you find that the ends of the nerves are bulbous That condition which you see in stumps is found in the upper end of every divided nerve If you look at these specimens they will give you a correct idea of this condition of the proximal end These bulbs were always supposed to be formed of fibrous tissue until 20 years or more ago it was pointed out that in them there are a large number of nerve fibres and further investigation showed that these nerve fibres are young and that they have been formed in the distal end of this portion of cut nerve. They are not old fibres which are in a state of atrophy The first effect, however of cutting a nerve is that the extreme peripheral portion of the proximal end undergoes degeneration and it is only after this degeneration has been completed that a regeneration occurs exactly similar to that in the distal end, of which I shall say more directly It is, then, after this degeneration that regeneration of the nerve fibres takes place, new nerve fibres being developed from the nuclei of the sheath or neurilemma. No other change takes place in the proximal end of a divided nerve if within a reasonable length of time an opportunity be given for the two ends to join together But if, on the other hand the nerve ends are not united if they do not have the opportunity of coming together and if the divided nerve fibres which are cut off from the distal muscles and skin do not have the opportunity of resuming their function, they afterwards undergo changes which at the present time are largely lost sight of but which are of the utmost importance in considering the question of secondary nerve suture. You know that it is a rule in pathology that a part which is not used undergoes atrophy And this is true of nerves as well as of any other structure. The consequence is that the proximal end of the divided nerve undergoes atrophy in proportion as the fibres are cut off from the parts which they have hitherto innervated. The result is that after the lapse of years the proximal portions of the divided nerves gradually shrink in size and it is probable that this shrinkage is associated with actual destruction of a certain amount of the nerve fibres and of the axis cylinders which are their essential parts. But something more than that happens, and it was pointed out many years ago that after amputation there ensue in the spinal cord changes which result in destruction and atrophy of some of the large motor cells in the anterior cornua. It is only to be expected that if these cells are separated from the muscles which they have been in the habit of innervating they also should undergo atrophy But it is of much importance to recognise that changes take place as far up as the spinal cord, and changes such as the destruction of the large nerve cells in cases in which amputation has been performed are of the greatest importance to recognise And it is believed and is thought to have been proved by experiment, that exactly the same changes take place when merely a nerve has been divided and not only when the limb has been amputated. This has been proved in the case of animals by experiment, but as far as I know it has not been proved in the case of man though it is probable that this atrophy of large nerve cells which undoubtedly occurs after amputations occurs also after mere section of a nerve, in cases where years have elapsed and the nerve has not rejoined

We will now pass to a consideration of the lower end of the nerve. The immediate effect of section of a nerve is that the whole of the lower end undergoes both rapid degeneration and atrophy so that ultimately the whole of the peripheral part of the nerve is destroyed The immediate effect is, that within a very few days there is a destruction or breaking up of the myeline, which is commonly talked of as "segmentation of the myeline." The myeline, instead of forming a continuous sheath around the axis cylinder collects in droplets here and there in the sheath At the end of about three weeks the greater part of the myeline is broken up and taken away and at the end of five or six weeks there is practically no myeline to be seen. Before this destruction of myeline is complete the axis cylinders also have begun to disintegrate and to break up and in the course of a short time they are completely destroyed so that at the end of five or six weeks the nerve in the whole of its peripheral part is reduced to its original fibrous tissue elements. There is the neurilemma sheath intact, there is the sheath of the nerve without the essential nerve elements and that condition is one which you will find in every completely divided nerve within five or six weeks. What is not so clear is the next step after this. I have told you that in the lowest part of the proximal end of a divided nerve there is first of all this same degeneration and that very soon there is the growth of a bulb and that this bulb contains newly formed nerve fibres. Is there ever a bulb on the lower end of the nerve? No, there is not. There is no separate formation of nerve fibres at the cut end of the peripheral portion such as occurs in the proximal end Next, is there a restoration of nerve fibres in the peripheral end of the nerve apart from union with the upper end of the nerve? For many years it was believed after Waller had shown that the section of a nerve was followed by its degeneration that the only way in which new nerve fibres could grow in this peripheral end of a divided nerve was by an extension of pre-existing fibres from the upper end, which worked their way down in a corkscrew fashion and grew until they occupied the sheaths which previously had been occupied by normal nerve fibres but which were now empty in the peripheral end. That was mostly a theoretical explanation and was never really demonstrated. Afterwards when the peripheral ends of these nerves came to be more carefully examined it was shown that, at any rate in many animals, there was the formation of nerve fibres of an imperfect character in the peripheral end and something like 20 years ago I found this same condition in the nerve fibres of man. I will read you a brief extract of some lectures I delivered at the Royal College of Surgeons in the year 1887 and which I published in The Lancet[1] and afterwards in a book on "Injuries of Nerves" as follows —

> Chief in importance amongst the changes in the peripheral end is the regeneration which occurs even when no union has taken place with the proximal end. ... .. In the case of a lad of 18 in whom an operation for re-union of a divided ulnar nerve was undertaken seven months after injury an examination of the peripheral end showed that scattered about a transverse section were several small imperfectly developed nerve fibres—smaller than natural and their myeline sheath scarcely perceptible ...... In the case of a woman, aged 53, who had divided the median nerve nine months previously I found the circular spaces in the neurilemma occupied by nerve fibres in various stages of regeneration. The steps in the formation of these fibres could moreover be most clearly traced Their first appearance was in the form of oval and spindle-celled nuclei which seemed to be identical in structure with the nuclei of the sheath. The next step was the elongation of the nuclei and their gradual transformation into fibres around which subsequently a myeline sheath was formed ..... I have been unable to find that similar changes had been noticed by other investigators in cases of nerve section in man. The conclusions that may be drawn from the most recent investigations are: (1) The nuclei of the sheath of Schwann form the new axis by union; (2) the myeline is subsequently formed; (3) the peripheral end may become regenerated without forming any union with the proximal extremity but that it again tends to regenerate if union fails

---

[1] The Lancet April 30th, 1887 p 863.

It is 16 years since these extracts were published, and ever since then the doctrine of the peripheral regeneration of nerves has been taught in this school It has also been gradually adopted by almost all surgeons, for clinical experience of injuries in man was evidently in such a matter as this of much greater importance than any observations on animals could possibly be, and it was noticed, soon after nerve suture became part of surgical practice, that if you sewed together the two ends of a nerve which had been separated for several months, then, almost directly after the two ends had been brought together, and often within a few hours, sensation was restored Now, it was evidently impossible that sensation could be restored by the joining together of an upper end which contained normal fibres and a lower end which contained no fibres at all. Therefore it was evident that the regeneration of the peripheral end must have proceeded to some extent in order that there might be fibres sufficient to carry any sensation within a few hours after nerve suture, for nobody could suggest that within those few hours newly formed nerve fibres had extended along the whole length of the peripheral portion of the divided nerve. So that surgeons very soon came to accept as a truth, and almost as a truism, that the peripheral end of a divided nerve did regenerate independently of its union to the upper end

The next thing to consider is, To what extent does it regenerate? It regenerates to a great extent, but never to the full extent without union with the proximal end. The new nerve fibres which I have mentioned as being found in the peripheral ends of divided nerves never attain maturity, they never grow to their fullest size, and I question if they ever grow to their fullest numbers without being joined to the upper end, and union with the latter also results in a much more rapid as well as a more complete regeneration.

The next point which we will consider is, Do these new nerve fibres also, as do the nerve fibres in the proximal end, undergo a second atrophy if they do not join the upper end, and if for years they are not used? I have no doubt that they do I have no doubt that after regeneration, if union with the upper end does not take place, atrophy necessarily ensues, for it has been found that years after complete want of union the distal ends of divided nerves are extremely shrunken, and it has been proved that there is a time after which secondary suture of a divided nerve does not result in a great deal of gain. But I will say more about that point when we consider the question of treatment.

Lastly, we have to consider what happens between the two ends of the nerve I have told you what happens in the proximal end and I have described in general terms what happens in the distal end. You have now to consider what occurs between the two ends If the two ends are in close apposition there are formed new axis cylinders and new nerve tissues which unite the two ends, much as the permanent callus unites a fracture. And it is also possible for the ends to be united even though they are a little distance apart. I take it that if they are a considerable distance apart no useful union ever results If they are an inch or more apart certainly no useful union ever ensues But if they are at a distance of a quarter of an inch from each other a good deal of union may result, and surgeons know that in cases where they have divided sensory nerves upon the face with the intention that they shall not unite unfortunately there is a great tendency for them to unite, even although the ends are fairly widely separated There is a tendency for sensory fibres, at any rate, to creep across an intervening space. I am afraid that there is no such tendency for motor fibres to do so to a useful extent, and consequently in many cases where mixed nerves have been cut, although there is some return of sensation even though the ends are not in close contact, there is, on the other hand, seldom any return of muscular power unless the ends are closely coapted.

Next let us turn to the further effects of injury of nerves Let us go to the tissues which they supply, and first of all to the muscles As soon as a nerve is divided the muscles which it supplies are immediately paralysed and they remain permanently paralysed if the nerve is not reunited at some time before complete atrophy and changes in the cord have taken place. The muscles that are paralysed undergo changes which are very similar to, and may be compared with, those which occur in the peripheral end of a divided nerve They undergo rapid degeneration as well as atrophy, it is not merely that the muscular fibres, on account of not being used, atrophy, but that the muscular fibres, being cut off from their centres of innervation, rapidly degenerate, with th result that in a comparatively few weeks muscles which wer formerly of good bulk are reduced pretty much to fibrou tissue. I will not trouble you with the details of the microscopical changes which take place in cases of section or motor nerves But the result is very well seen in such a cast of the hand as I show you It is still better seen in this photograph of the hand the ulnar nerve of which has been divided. Within a few weeks all healthy muscular tissue is gone It is not merely that the muscle fibres get less numerous but that all the muscle fibres undergo degenerative change. True atrophy is really a diminution in size without alteration in structure, but here there are both atrophy and degeneration, an alteration in structure for the worse Now, these muscles will not be re made unless the continuity of the nerve is re established There can be no doubt about that. The independent regeneration, to a certain extent, of the distal end of a divided nerve may be considered to be a fact. But it is also a fact that a similar regeneration of the muscle does not take place. The next thing one is tempted to ask is this, Are those nerve fibres which you see regenerated in the peripheral end of a divided nerve, sensory fibres, or are they motor fibres? It is certain that the sensory fibres are regenerated in the peripheral end of a divided nerve independently of union with the upper end To what extent are motor fibres regenerated? This question is forced upon us by the fact that, although there is a formation of new nerve fibre in the peripheral end of the divided nerve there are no corresponding regeneration and restoration of muscle. And it is impossible to prove whether these regenerated fibres seen in the distal end of a mixed nerve which has been divided are motor or sensory fibres, for there is no way of distinguishing a motor from a sensory fibre in process of formation, even under the microscope My own opinion is that it is probable that the motor fibres do not undergo anything like the same complete, or nearly complete, regeneration that the sensory fibres do, and I think that clinical evidence supports this view

Supposing that a nerve is divided and the muscles are paralysed and wasted, what clinical evidence is there of this condition? In the first place, there is loss of power, or paralysis Next, there result in time certain deformities, and these deformities are due to one of two things—either to the weakness of the muscles which are paralysed, resulting in the parts being displaced by healthy muscles, as in the characteristic deformity after division of the ulnar nerve, or there may be actual shrinkage of the muscle, not only in its bulk and thickness but in its length If it is allowed to shrink so that its ends are approximated and if a part like the hand or the wrist is kept in a position of flexion whilst the flexor muscles waste there will be deformity due to contracture of the wasted muscles and not deformity from displacement of the part by the healthy muscles So that deformities may result either by the action of healthy muscles not being opposed by the paralysed ones or by the contraction and shrinkage of the atrophied muscles And this condition is particularly liable to occur if a part is kept in such a position that the origins and insertions of muscles are approximated during this process of contracture

Next, what evidence is there, clinically that these changes are taking place? Further evidence is supplied by the reactions to electricity Within two or three days of a nerve being divided the muscles that it supplies begin to lose their faradic contractility, from four to six days after division the muscles have actually lost their faradic contractility Then with regard to galvanism the galvanic contractility is retained for a very much greater length of time It may remain as long as from four to six weeks—in rare cases it remains for about two or three months, but after that lapse of time galvanic irritability is entirely absent and the muscles no longer react to galvanism You have to be careful in estimating this condition, because if you are testing muscles in a part like the hand it is a little difficult to separate, by noting the electrical reactions, the muscles supplied by the ulnar from the muscles supplied by the median nerve, and consequently if you are not careful you find that the reactions are not as clear and definite as I have said they are. But what I have told you is a result of examinations of the muscles in cases of section of nerves a good many hundreds of times, and in all of them the muscles have been examined either by Dr H. Lewis Jones or by his predecessor Dr W Steavenson, both of them skilled electricians. I think, therefore you may take it as certain that the statements which I have made are correct.

The next thing to consider is, Supposing that the divided nerve does unite reasonably soon, which returns first—motor power or faradic irritability or galvanic irritability? There is no doubt about that point. It is of importance to remember that voluntary power returns weeks, months, or even a year before faradic and galvanic irritability return at all. That is a matter of considerable importance when you are examining a patient, for the first sign of restoration of muscular power and of the formation of new motor nerve fibres is not to be found by examining the muscle with faradism or galvanism. You will find that voluntary power will return first of all and that not until after the man has had the use of the muscle and it has been restored in bulk to a considerable extent will *electrical reactions* even begin to be restored. Faradic contractility generally returns before galvanic. That electrical reactions are so delayed is very curious, but still it is a fact and it is one of clinical importance. So whilst the electrical reactions are of great interest and use in estimating the extent of injury of a nerve and the amount of paralysis of muscle they are not of a corresponding use in estimating the return of power because the return of power can be observed clinically and the patient himself is conscious of it long before electricity will give any indication that nerves have been restored or muscles re made. I shall have something more to say about that in connexion with suture, but what I have given you are the elementary *facts* which you must grasp in order to understand the clinical application of them.

In addition to changes in the muscle there are changes which take place in other tissues supplied by nerves, for of course nerves supply all the different tissues. *Let us* take the hand The nerves of the hand are so commonly injured and the hand is a part of the body of such immense importance that it is as well to study these conditions in this part of the body Let us look at the skin. Here are paintings of the skin of both of the hands of the same patient. In the one the median nerve has been divided, in the other there is a normal skin. In the hand in which the nerve has been divided the fingers are thin and glossy shiny and tapering Notice that all the markings on the skin of the fingers are gone. The skin looks as if it had shrunk, as if it were tied down tightly and stretched upon the subjacent structures. This, indeed, is so. The skin is as shrunken and *atrophied as it looks*. Here is another hand which shows the same thing to a less extent. This next picture shows a patient in whom the left median nerve was divided some time previously Here you see the characteristic tapering shiny fingers and the other condition of skin which was described years ago by Sir James Paget under the name glossy skin." This glossy shiny atrophied skin is very characteristic of many nerve sections. Sometimes the changes which take place in the skin are more pronounced even than that. Here are two pictures. In this left hand there is shown a change in the index finger after division of the median nerve at the wrist. You will notice that the skin is raw that there has been desquamation of epidermis and that as *a result* the whole of the finger is sore. Those are changes which are rare, but the shiny atrophied skin is common. Now look at the next picture and see to what extent these changes may go. This shows the result of division of the median nerve and you see that *the end of the* index finger has completely ulcerated away and there is left the exposed tip of the necrosed phalanx. Patients who have these divided nerves are liable to have painless whitlows, for the part is insensitive, and these whitlows tend to cause destruction of the end of the finger and may result in necrosis of the phalanx Not a few of these conditions are the results of injury to a part which is insensitive. A man came here with an open sore at the end of his index *finger* as a result of his having put it into the bowl of his pipe he had pressed the burning tobacco down without noticing that he burnt his skin Another man said that he burnt his finger by putting it against a stove but he did not know that he burnt it until after he had taken it away In the same way slight cuts or tears are often inflicted upon these anæsthetic fingers without the patient being aware of the injury Of course, a slight injury which causes no pain is liable to be neglected by the patient and the consequence is that a small sore place is not treated because it does not hurt, and so the result is that the sore place gets bigger instead of healing

Now the nails are really appendages of the skin and it is quite proper to consider them in connexion with the skin The nails in such cases as we are considering become very broken and fibrous they are ridged and furrowed, altered completely in their texture. It seldom happens that a nerve supplying the hand is divided without there being in the course of a few weeks or months, some changes in the structure and texture of the nails. In this case there had been division of the median nerve at the wrist some time previously, and you see that the nails are much more like birds talons than ordinary nails, they are large, thick, curved and fibrous.

The hair is another appendage of the skin. In many cases the hair atrophies like other structures, and so do the glandular tissues in the skin, the sebaceous glands and the sweat glands, and it is because of the atrophy of these *structures that the part assumes this shrunken shrivelled*, glossy appearance. I take it that that condition of the skin which is talked of as glossy skin" is not merely a result of change in the skin but of changes in the corresponding glands, indeed of all the constituent parts

Lastly, we will consider the joints. The joints undergo changes which result in their becoming more or less stiff. They often have fibrous adhesions formed in them and first of all they generally undergo an inflammatory change. If you look at the joints of the hand in a case where the ulnar or median nerve has been divided you will find soon after division that the joints are swollen and painful, and that afterwards, when the inflammation has passed by and the swelling has gone, they are left more or less stiff. This stiffening of joints is a matter of clinical importance, for if you do not recognise it and take care that the joints do not become stiffened then in many cases the condition of the *hand will be much worse than it need have been*, for you can anticipate these changes and can to a great extent, prevent deformities which might otherwise arise.

EFFECTS OF SUTURE.

And now we will consider what happens, supposing that as soon as a nerve is divided you suture the two ends together Do those two ends ever grow together immediately so that none of these degenerative changes which we have been describing occur? No, it never happens Unfortunately there is no such thing as the immediate and complete union of two ends of a divided nerve. I am not prepared to say that this may not take place to some slight extent, but that is a matter rather of theoretical than of *practical importance*. It is certain that after a nerve has been divided even if you suture it within an hour even if you divide it at the time of operation and suture it yourself within a few minutes of having divided it, you will not prevent most of the degeneration which takes place in the peripheral end. You may cause some diminution in that degeneration possibly and it may be that suture may prevent to a slight extent the degenerative changes which I have described, but unfortunately it certainly does not prevent the changes that take place in the muscles. They will still show the alterations of the electrical reactions, they will waste and they will degenerate. The same is true of the peripheral end of the nerve. It will atrophy and *degenerate* and *new nerve* fibres will have to be made The consequence is that when you have to do with a patient who has a recently divided nerve however carefully you suture it and however well the wound behaves you must expect, and your patient must be told to expect, that the motor function of the nerve will not be fully restored for about a year or more. Supposing that the nerve has been divided that it has been sutured as carefully as possible, that the wound has run an aseptic course, and that all has healed well which returns first, motion or sensation? Undoubtedly sensation returns first. Sensation returns, and may become comparatively complete, months before there is the slightest evidence of the restoration of motor power The muscles if they waste *necessarily* take time to be restored. The sensory structures do not take anything like the same time nor do they require the same amount of repair The destruction of tissue in the sensory apparatus does not correspond with that in the motor and the consequence is that the muscular tissue requires so much longer time to be re-made that motor power is always later in returning than is sensation.

PRIMARY SUTURE

Now a very few words about primary suture which is best carried out as soon after a nerve has been divided as possible. In most cases it is best, in suturing a nerve, to pass at least one suture, consisting of a material which will be absorbed, right through the nerve, above and below where it is divided Personally, I think that the best material you can use is a tendon suture, generally quite a fine one, such as a split kangaroo tendon. I object to silk, because it remains as a foreign body in the nerve and causes the formation of fibrous tissue and consequently a lumpiness and hardness and tenderness in the sutured nerve. A tendon suture will last a long time and is strong and yet ultimately it will be completely removed. One suture is in many cases sufficient and causes quite enough coaptation of the parts In a certain number of cases you may put one or two fine sutures in addition through the sheath of the nerve, but I think that, as a rule, these are not necessary Having done this and put the part at rest on a suitable splint you have done practically all that operation can do to bring about union of the upper and lower ends of the nerve. After that the important thing is to keep the parts sufficiently long at rest and not to put a strain too soon upon the nerve which has been joined. Then there should be warmth, slight use of the part, massage, and galvanism Warmth is undoubtedly useful. A paralysed part tends to remain cold and the more cold it is the more you may be sure that the processes of nutrition are impaired. Therefore warmth is distinctly indicated. Again, if a part is paralysed and cannot move of itself you will help its nutrition by massage, which will at any rate prevent some of the contracture of muscles and prevent stiffening of joints and will tend to move on the fluids in the tissues and in that way maintain to some extent their nutrition. Again, so long as there is muscle to galvanise the use of the galvanic current will at any rate give the muscle something to do and keep it moving and prevent a little its atrophying by disuse and will cause such muscular fibres as there are to contract. Warmth, massage, and galvanism are not indispensable, but they tend to keep the tissues supplied by the nerve in a more healthy condition.

Now, having cut across the nerve and sewn it together, what happens to individual fibres? Do they rejoin? Is it to be supposed that they re-unite so that the proximal end of a fibre rejoins the distal end of the same fibre? This is evidently impossible No one supposes that the fibres in the peripheral part of a nerve twig which goes to the ulnar side of the little finger are going to seek out and join to the same fibrils in the proximal part with which they were previously continuous. I take it that it is certain that the proximal end of a nerve which went to the middle finger may join the distal end of the nerve which went to the thumb and—speaking of sensory nerves—that the nerves must get very much mixed up As a matter of fact, the result is that at first, although the person can feel that he is being touched, yet he is not in the early stage able to localise exactly For instance, you may touch a man's index finger in front and he may tell you that you are touching the back of his middle finger Evidently the nerve fibres cannot be expected to join in the same position as that in which they were before the injury

What about the motor fibres? That is a much more complex matter The motor fibres also, no doubt, get mixed, and, when you come to consider it, it is evident that a good many motor fibres do not necessarily get properly joined up at all, and the result is, that though you may talk of successful union of a nerve, it is most likely that even in the most successful cases all the sensory fibres do not get joined up nor do all the motor fibres As a practical result, surgically speaking, as far as your patients are concerned, there is evidence that even in these successful cases there is not that complete restoration of nerve tissue which would be implied in the term "cured" The patient is not usually cured completely, for the part is often not innervated as it was before the injury But I shall have more to say about this in connexion with injuries of different nerves, for in certain nerves function is much more completely and rapidly restored than in others

---

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN —A quarterly court of the directors of this society was held on July 9th. The President, Mr Christopher Heath, took the chair Two new members were elected the deaths of three members were reported, and the resignation of a member was accepted Fresh applications for grants were read from two widows and grants of £50 per annum were made. It was resolved to distribute £1342 among the 55 widows, 11 orphans, and five recipients from the Copeland Fund now in receipt of grants. The expenses of the quarter were £47 19*s* 6*d*.

Five Clinical Lectures

ON

THE CAUSATION AND PREVENTION OF PHTHISIS.

BY BYROM BRAMWELL, M D, F R C P, F R S EDIN,

PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY, &C

LECTURE III.[1]

GENTLEMEN,—To-day I propose to direct your attention to (1) the precautions which the individual should take in order to protect himself against phthisis and other forms of tuberculous disease, and (2) the measures which, in my opinion, the municipal sanitary authorities and the Government should take with the object of trying to reduce the prevalence of phthisis and other forms of tuberculous disease to the lowest attainable limit

THE PRECAUTIONS WHICH THE INDIVIDUAL SHOULD TAKE IN ORDER TO PROTECT HIMSELF AGAINST PHTHISIS AND OTHER FORMS OF TUBERCULOUS DISEASE.

With this object in view the individual should endeavour (1) to increase his "vital resistance" by maintaining his general health in the best possible state of efficiency, (2) to avoid all conditions likely to produce in the body, and more especially in the respiratory and gastro intestinal tracts, the local alterations which form a suitable nidus for the development and growth or absorption of the tubercle bacillus and its spores, and *a fortiori*, if such alterations are present, to take means to allay and to remove them as speedily and as completely as possible, and (3) to prevent the introduction into the system of the tubercle bacillus and its spores—in particular (*a*) to avoid breathing air containing the tubercle bacillus or its spores, and (*b*) to avoid drinking milk containing living tubercle bacilli or their spores These precautions are especially necessary in the case of persons who inherit a strong hereditary tendency to phthisis and tubercle, and still more essential in the case of persons who are obliged to live in close contact with persons suffering from phthisis

During infancy and childhood special attention should be directed to the dietary and to the condition of the gastro-intestinal tract. Everything (such as unsuitable food, decomposing milk, dirty feeding-bottles, insanitary surroundings, or exposure to cold and damp) likely to produce irritation and catarrh of the gastro intestinal tract should be carefully guarded against since such lesions form a suitable nidus for the development and growth of the tubercle bacillus and favour its absorption. If catarrhal lesions or diseased conditions are developed in the gastro intestinal tract they should be allayed—treated and cured—as speedily as possible, for there seems reason to suppose that one of the reasons why the children of the poor suffer so much more frequently from tabes mesenterica and other tuberculous lesions, such as tuberculous meningitis, than the children of the rich is that (in consequence of their poverty, the insanitary nature of their surroundings, the careless way in which they are fed, and the unsuitable nature of their food) they are much more frequently the subjects of catarrhal and diseased conditions of the gastro-intestinal tract than children who are better circumstanced and looked after Special efforts should also be made to prevent the introduction into the gastro-intestinal tract of tuberculous milk. During later childhood the same precautions should be maintained and special attention should be directed to the condition of the mouth and throat, since diseased conditions of the mouth and throat are apt to lead to the production of tuberculous lesions in the cervical and sub-maxillary glands and more distant organs, both by causing irritation of the cervical glands (i.e., by producing a suitable nidus for the development of the tubercle bacillus) and by favouring the absorption of the tubercle bacillus or its spores During youth and adult life special precautions should be directed to the condition of the respiratory apparatus. If the respiratory capacity is, in consequence of defective chest development below par it should be increased by suitable gymnastic exercises and special care should be taken to prevent the development in the respiratory tract of unhealthy conditions and catarrhal lesions for it is during this period (youth and adult life) that phthisis is chiefly apt to develop

---

[1] Lectures I and II were published in THE LANCET of July 5th (p 6) and July 12th, 1902 (p 61) respectively

Persons who inherit a strong tendency to phthisis should with the object of preventing the development of it and other forms of tuberculous disease, be well fed well clothed, and well housed, they should live, if possible, in a high, dry and pure atmosphere, and in a well built, airy and well-drained house, which is not built on a cold and damp subsoil, which is surrounded by plenty of fresh air and which is bathed in plenty of sunlight they should have plenty of exercise and sleep, their bedrooms should be airy and well ventilated they should make a practice in winter as well as in summer of sleeping with the window open (a few inches from the top is amply sufficient) they should avoid excesses of all kinds (alcoholic and other) they should choose an occupation or profession which does not necessitate the breathing of an irritating and dusty atmosphere (the mortality from phthisis amongst knife-grinders and stonemasons for example, is very high) an occupation which is outdoor and active rather than indoor and sedentary If their chest development is defective they should systematically practise lung gymnastics with the object of increasing their respiratory capacity and they should be regularly weighed, for there is no better indication of variations in the state of nutrition than variations in weight. They should pay special attention to the condition of their digestive functions they should drink plenty of (non tuberculous) milk they should eat if they are able to digest it a good deal of butter and fat-forming foods, and if their nutrition is below par they should take cod liver oil in cold weather

It is unnecessary to say that many of these prophylactic measures the object of which is to maintain the general health in the best possible state of efficiency to strengthen and increase the "vital resistance," and to prevent the development of those local alterations in the respiratory and gastro-intestinal tracts which form a suitable nidus for the development of the tubercle bacillus, or favour its absorption can only be satisfactorily carried out by rich and well to-do people. I have, however detailed and emphasised them, since they are of the utmost importance and since they should, so far as circumstances will permit be aimed at and carried out in the case of the poor as well as in the case of the rich.

THE SPECIAL PRECAUTIONS WHICH SHOULD BE TAKEN BY HEALTHY PERSONS LIVING IN CLOSE CONTACT WITH PHTHISICAL PATIENTS

Healthy persons who are obliged to live in contact with patients suffering from phthisis should be specially careful to carry out the individual precautions which have just been insisted upon. And it is important to emphasise the fact that many of the precautionary measures which are best fitted to prevent the extension of the disease to other (healthy) persons who are in close contact with the phthisical patient and also to the public at large (such as free ventilation abundance of fresh air the avoidance of overcrowding plenty of sunlight, scrupulous cleanliness both as regards their own persons and their surroundings, the absence of dust and dirt, the destruction or disinfection of all discharges containing the tubercle bacillus, &c.), are also of the first importance to the phthisical patient himself—i.e. are amongst some of the most important measures which he should adopt with the object of promoting the cure or arrest of his disease and to prevent the further development of secondary tuberculous lesions in his own body It is important to impress this fact upon the patients and upon the public for many persons who will not adopt precautionary measures merely for the benefit of the outside public will adopt precautionary measures if they realise that it is for their own benefit and for the benefit of their wives and children that they should do so.

Persons living in close contact with phthisical patients should be scrupulously careful to take every means to prevent the introduction of the tubercle bacillus or its spores into their own bodies. The chief risk is the inhalation of air containing the tubercle bacillus or its spores or infection by kissing using cups &c., contaminated with phthisical sputum or other discharges containing the tubercle bacillus The essential points are to destroy the sputa or other discharges which contain the tubercle bacillus and its spores while they are still moist—i e., as soon as possible after they are ejected by the patient—to prevent such discharges becoming dried and pulverised to see that the rooms in which phthisical patients live and sleep are kept scrupulously clean thoroughly well ventilated and if possible, bathed in sunlight, so that the poison, if it should get into the atmosphere, may be freely diluted and destroyed by oxygen and sunlight.

The destruction and disinfection of the sputum or other discharges which contain the tubercle bacillus.—The phthisical patient must be instructed not to swallow his sputum This is of great importance for the patient himself in order to prevent the development in the intestinal tract of secondary tuberculous lesions (tuberculous ulceration of the intestine) It is also of importance for his friends and relatives, for if diarrhœa the result of tuberculous ulceration of the intestine is developed the difficulty of destroying the poison is greatly increased and additional precautions against the extension of the disease to others are necessitated. In those cases of phthisis in which diarrhœa is developed the fæcal discharges should, immediately after their evacuation, be destroyed or disinfected and any linen bedclothes &c. which are soiled by such discharges should be immediately disinfected or destroyed In short, in cases of tuberculous diarrhœa, whether developed in the course of phthisis or any other form of tuberculous disease (tabes mesenterica acute tuberculosis &c.), the fæcal discharges should be treated in the same way as the fæcal discharges from a case of typhoid fever are treated—never allowed to become dry and pulverised always disinfected or destroyed immediately after their evacuation, the nurses and attendants being scrupulously careful to wash their hands after attendance on the patient, before eating &c. The phthisical patient should be instructed to expectorate into a vessel containing a disinfectant or into a pocket-handkerchief which can be destroyed (burnt) after being used (a handkerchief of Japanese paper answers well) and never on any account to expectorate on the floor bedclothes, in the public streets, on the floors of cabs omnibuses, tram cars, railway carriages, &c. In advanced cases of phthisis the patient and his friends should be instructed not to allow the sputum to remain dry on the lips, beard moustache, &c. The phthisical patient should be instructed never to kiss any healthy (unaffected) child or in fact any healthy person and *vice versâ* healthy persons should not allow themselves to be kissed by persons suffering from phthisis It is hardly necessary to say that this is one of the precautionary measures which will in many cases be evaded.

The rooms in which phthisical patients live should be kept scrupulously clean. No dust should be allowed to accumulate in them—the floors walls &c. should from time to time, be rubbed over with a damp cloth. We have seen that the inhalation of dust tends to produce in the respiratory tract catarrhal and other conditions which form a suitable nidus for the development of the tubercle bacillus and that the inhalation of dust which contains living tubercle bacilli or their spores is the chief means by which the tubercle bacillus is conveyed from one human being to another This is another of the precautionary measures which in practice it is in many cases very difficult to carry out. Free ventilation is of the greatest importance (1) for the health of the patient himself and of the other (healthy) occupants who live or work with him (2) in order that the poison if any pulverised sputum or other discharges should get into the atmosphere, may be freely diluted and (3) with the object of destroying any tubercle bacilli or their spores which may be present in the atmosphere or in the dust on the walls floor &c. since an abundant supply of oxygen is destructive to the vitality of the tubercle bacillus. For the same reasons (for the health of the phthisical patient and the other inmates and with the object of destroying the tubercle bacillus) as much sunlight as possible is desirable.

Healthy and unaffected persons should not (if it can be prevented) sleep in the same room,[2] and should never sleep in the same bed, with phthisical patients Overcrowding of the rooms, houses, and workshops in which phthisical patients live and work should, as far as is possible, be prevented. If a phthisical patient should cough into the face of a healthy person, his nurse, or medical attendant, the healthy person should immediately blow the nose, so as to clear out the nostrils and rinse out the mouth and throat with some disinfecting solution. All discharges from tuberculous cases (discharges from diseased bones, joints, glands, &c.) should be treated in the same way as the sputum—i.e., immediately disinfected or destroyed.

---

[2] This statement does not of course apply to hospital wards, in which due precautions as regards ventilation cleanliness and the

THE ADMINISTRATIVE CONTROL OF PHTHISIS

The points to which the municipal and sanitary authorities should direct attention and the measures which they should employ with the object of reducing the prevalence of phthisis and other forms of tuberculous disease to the lowest possible limit obtainable with our present means of prevention are, in my opinion, as follows.[3]

General sanitary measures.—It may be laid down as a general proposition that anything which raises the tone and health of the individual, and of the community as a whole, increases the "vital resistance" against tubercle and therefore tends to protect the individual and the community against it, and *vice versâ* that anything which depresses the health of the individual or of the community as a whole decreases the "vital resistance" against tubercle and tends to favour the development and to promote the extension of the disease. Hence general sanitary measures are of the greatest importance in preventing the development of phthisis and other forms of tuberculous disease. The enormous decrease in the mortality from phthisis and other forms of tuberculous disease (tabes mesenterica apparently excepted) which has taken place during the past 45 or 50 years has without doubt been chiefly due to the great attention which has been paid to general sanitary measures and to the diminution of poverty, the cheapening of food, and the general advancement in the well being and whole surroundings of the poorer classes. I shall not attempt to enter into details with regard to the general sanitary measures included under this head, but the following may be enumerated: the laying out of the streets, the construction of dwellings, common stairs, workshops, &c., with special reference to providing sufficient air space both outside and inside, free ventilation, and, so far as it can be provided, a copious supply of sunlight, attention to drainage and the avoidance of damp, the cleansing of streets, alleys, courts, houses, workshops, &c., the removal of filth, dirt, dust, &c., the provision of an ample supply of pure water, the destruction and removal of insanitary houses, slums, &c., the suppression of nuisances, the prevention of overcrowding, &c.

As I have already pointed out, everything which tends to eliminate poverty, to promote the well being, and to raise the moral tone of the community necessarily has an important influence in the prevention of phthisis and other forms of tuberculous disease. Further, it should be remembered that many of the general sanitary measures which improve the health of the community, since they remove the conditions (such as darkness, dampness, a deficiency of sunlight, and a deficient supply of oxygen) which favour the continued vitality of the tubercle bacillus and its spores outside the body, may be regarded as measures specially directed against tubercle. I repeat that everything which tends to promote the health and well being of the community tends to prevent the development of phthisis, and *vice versâ* that everything which reduces the health and depresses the vitality of the community tends to favour the production of phthisis. Under the latter head the following conditions may be specified: poverty and destitution, deficient food, improper food, insufficient clothing, overcrowding, defective ventilation, rebreathing the expired air, darkness, absence of sunlight, dampness of dwellings, dampness of subsoil, defective drainage, the presence of dust, dirt, and filth, alcoholic or other excesses, and consequently a low moral tone of the community, &c. The removal of some of these conditions is not, of course, the duty of the municipal and sanitary authorities, but many of them hang more or less closely together, and the removal of the one—the sanitary defects—tends, at the same time, to the removal of the other—the moral defects, poverty, &c., and *vice versa*.

Special preventive measures.—I shall now speak of the special precautions in the localities, workshops, houses, and rooms in which phthisical patients live and work. If general sanitary measures applied over the whole sanitary area are important means of protecting the healthy members of the community against phthisis and of diminishing the prevalence of the disease it is hardly necessary to point out that the same sanitary measures are of still more importance when focussed, as it were, on the points where they are most required—i.e., on the rooms, houses, workshops, and localities in which patients affected with phthisis live and work. Consequently, it is, theoretically at least, the duty of the municipal and sanitary authorities to see that the rooms, houses, and workshops in which phthisical patients live and work are not in an insanitary condition and that any obvious and marked insanitary conditions (such as great overcrowding, highly defective ventilation, the accumulation of dirt and filth, &c.) which predispose the healthy inmates to phthisis are, so far as this can be effected by the action or advice of the municipal and sanitary authorities, removed. It is also the duty of the municipal and sanitary authorities to do what they can to instruct the public, and especially persons suffering from phthisis and the healthy people with whom they are in immediate contact (their wives, families, &c.), as to (1) the nature of phthisis and tubercle, the channels through which the tubercle bacillus is introduced into the system, the conditions which favour the development of phthisis and tubercle, and the conditions which retard or prevent their development, &c.; (2) the importance of diligently and strictly attending to general sanitary conditions (ventilation, both of their day rooms and bedrooms, cleanliness, avoidance of dust, the importance of an abundance of fresh air and sunlight, of good feeding, &c.), in order that persons affected with phthisis may, so far as their circumstances permit, place themselves in the best possible condition to promote a cure of their disease; and (3) the precautions which patients affected with phthisis should take to prevent the extension of the disease to the persons with whom they are in immediate contact and to the public generally. Under this head, in addition to the points which have already been indicated in the preceding headings, the following should be emphatically insisted upon: the paramount importance of disinfecting or destroying the sputum while it is still moist—i.e., as soon after it is ejected as possible; the inadvisability of a healthy person sleeping in the same room and the danger of a healthy person sleeping in the same bed with a patient affected with phthisis; the risk which a healthy person may incur from being kissed by a person affected with phthisis; the risk that a healthy person may run from drinking out of the same cup, using the same spoon (unless they should have been carefully and thoroughly cleansed or disinfected) as a phthisical patient; the advisability of boiling milk before it is drunk, &c.

There can be no question that the great interest which the public are taking in the whole subject of tuberculosis is a most hopeful sign and that the increased knowledge which they are rapidly gaining of the nature of phthisis will be of the greatest possible benefit in enabling the profession and the municipal and sanitary authorities to cope with the disease. Consequently it is the duty not only of the profession but of the municipal and sanitary authorities throughout the country to do everything that they can to instruct the public, and especially the poorer members of the community, as to the nature of the disease and as to the measures which should be taken in order to cure and to prevent it. The diffusion of such knowledge (by medical men, by nurses, by clergymen, by district visitors, and by means of printed instructions, leaflets, &c.) will enable the healthy (unaffected) members of the community to protect themselves against phthisis in the future in a way which, for want of this knowledge, they have not been able to do in the past; it will enable patients suffering from phthisis to put themselves in the best possible conditions, so far as their circumstances and surroundings will allow, for curing the disease and for preventing the development of secondary tuberculous lesions in the intestine, &c.; it will do much to enable patients suffering from phthisis to prevent the extension of the disease to their wives and families and to the public at large, and it will, in the course of a short time so educate the public opinion that they will, I believe, not only submit, but, provided that they are convinced that such measures are essential and necessary will cheerfully submit, to the measures and restrictions which the profession, the municipal and sanitary authorities, and the Government may think necessary to impose in order to reduce the prevalence of phthisis and other forms of tuberculous disease in man to the lowest attainable limit and it is also to be hoped, in order to eradicate completely and to stamp out tuberculous disease in cattle.

---

[3] It must be distinctly understood that some of the measures which are suggested in the succeeding paragraphs, such as the compulsory notification of phthisis, the provision of laboratories for testing and reporting on the sputum, and the provision of hospital accommodation for dangerous cases of phthisis, are only suggested on the distinct proviso that a determined and vigorous effort is to be made to reduce the prevalence of the disease to the lowest attainable limit. Unless this is the object the large expenditure of money and the considerable sacrifices which they would necessarily entail both on the part of the healthy and on the part of many patients affected with phthisis would probably not be justified.

The importance of early diagnosis and treatment.—And here let me emphasise the facts (1) that, provided the proper measures of treatment are adopted phthisis is, in its early stages, curable in a much larger proportion of cases than was at one time supposed, (2) that in its later and advanced stages it is practically speaking an incurable disease, and consequently (3) that it is of the utmost importance that the disease should be recognised in its earliest stages in order that the appropriate means of treatment may be employed in the earliest and curable stage of the disease that effectual measures may be taken from the first to disinfect and to destroy the sputum, and that the places in which the disease is contracted may be located so that the rooms, houses and workshops which are sources of infection (phthisical centres) may be disinfected and put into a good sanitary condition. It is essential to remember that early diagnosis and treatment are of great importance not only for the patients themselves, but also for the healthy persons with whom they live and for the community at large. Every case of phthisis may (unless rigorous measures are taken to destroy and to disinfect the sputum) be a centre or source of infection to other people Every case which is not cured in its early stages is apt to run on and consequently may be a centre of infection for months and it may be for years. Hence the great importance, not only for the patient himself but for the healthy community (1) that the disease should be recognised in as early a stage as possible and (2) that all cases of the disease should be placed in the earliest possible stage of their development under the best possible conditions to promote a cure.

The provision at the public expense of means of testing and reporting on suspected sputum suspected milk, &c.—In the early stages of phthisis the diagnosis is often attended with considerable difficulty, and frequently the only means of deciding whether the case is one of phthisis or not is the detection of the tubercle bacillus in the sputum Now since the recognition of the disease in its earliest stages is of the greatest importance not only for the patient but also for the community it is in my opinion the duty of the municipal and sanitary authorities to provide means at the public cost for testing and reporting on the sputum of suspected cases of phthisis and on the discharges of other forms of suspected tuberculous disease. And since it is also in my opinion, the duty of the sanitary authorities to determine whether milk is tuberculous or not and to examine and report upon the discharges from suspected cases of typhoid fever diphtheria, cholera &c. every central municipal and sanitary authority throughout the country should provide a suitable laboratory under the charge of a skilled bacteriologist and an adequate staff of properly trained and skilled assistants for the examination of and reporting on such discharges (sputum, &c.) and food stuffs (milk, &c.) or should make arrangements with existing laboratories for this purpose.

The necessity of providing sanatoriums for the treatment of early cases of phthisis.—Modern experience has shown that fresh air sunlight good feeding and satisfactory surroundings are infinitely more important for the cure of phthisis than any form of medicinal treatment which has yet been introduced or devised hence the necessity of providing in every community sanatoriums in which cases of early phthisis can be treated and cured Now that the importance of the open-air treatment of phthisis is fully recognised rich people and those who are able to pay will take care to provide such sanatoriums for themselves, or rather I should perhaps say such sanatoriums will be provided in which phthisical patients who are able to pay will be received and treated. And it is highly desirable that such sanatoriums should also be provided for poor people. But in my opinion it is not the duty of the local sanitary authorities to provide such sanatoriums that, I conceive, is the duty of the charitable public and of the Poor law authorities. The sanitary authorities would not, in my opinion, be justified in spending the money of the ratepayers in providing hospital accommodation and sanatoriums for the treatment of cases of early phthisis, for provided that proper precautions are taken to destroy and to disinfect the sputum patients who are suffering from early phthisis are not dangerous to others The cost of providing sanatoriums and hospital accommodation for all cases of early phthisis would be enormous, while the cost of instructing phthisical patients as to the necessity of destroying the sputa (and if it is thought advisable of taking means, so far as this is practicable and possible, of seeing that these instructions are carried out) would be comparatively small As will be presently pointed out, phthisis differs from almost all of the other infectious and contagious diseases which are met with in this country in the important fact that the contagion can be thoroughly and easily controlled by the patient himself at all events in the earlier stages of the disease. All that he requires to do is to destroy or to disinfect the sputa, consequently it is not necessary so far as the prevention of the disease is concerned, to isolate cases of phthisis or to restrict the liberty of patients affected with phthisis at all events in the early stages of the disease, always provided that they (the patients) are willing to employ the necessary preventive measures—i.e. to destroy or to disinfect the sputa. But while it is not essential to isolate cases of early phthisis so far as the prevention of the disease is concerned it is very desirable, both for their own sakes—with the object of arresting and curing the disease—and for the prevention of the extension of the disease to others that cases of early phthisis occurring in the lower ranks of society at all events should for a time at least be placed in sanatoriums in order that the patients may be thoroughly taught the precautions which it is necessary to take with regard to the distribution of the sputum &c. to prevent the extension of the disease

The provision of hospital accommodation for dangerous cases.—But while in my opinion it is not the duty of the sanitary authority to provide sanatoriums for the reception of cases of early phthisis it is, I think, the duty of the sanitary authorities, either alone or in conjunction with the Poor law authorities to provide a certain amount of hospital accommodation for those patients affected with phthisis who, in consequence of their poverty the nature of their surroundings (defective house accommodation) and the advanced stage of their disease (great debility the presence of tuberculous diarrhoea for example) are quite unable to take the necessary precautions to prevent the extension of the disease to others and who may therefore be fairly regarded as distinct sources of danger to the community at large, and especially to the persons with whom they live in immediate contact.[4] Many poor patients who are suffering from advanced phthisis who are too ill to work, and who have no adequate means of support are only too glad to go to hospital and as a matter of fact many of these cases are at present of their own free will admitted to our hospitals and infirmaries—where they die This is I conceive one explanation of the fact (which at first sight seems curious) that in Edinburgh[5] Dundee and, I suppose, other large towns more phthisical patients die in two-roomed than in one roomed houses The very poor—those who live in one-roomed houses—die I suppose for the most part in hospitals or poorhouses the less poor—those who live in two-roomed houses—probably die in much larger proportions in their own homes. The migratory character of the very poor is probably also another cause of this difference.

Note.—17 deaths of persons who died in public institutions or common lodging houses are not included in the above

I repeat that, in my opinion, it is desirable that the nitary authorities, or the Poor law authorities, or the nitary authorities in conjunction with the Poor law uthorities (for, practically speaking, the cases of phthisis o which I am now referring are, in the great majority of nstances, paupers or very poor people), should provide a ertain amount of hospital accommodation for the reception, etention, and treatment of cases of this kind, for not nly are their surroundings eminently bad but they are nable to carry out proper preventive measures and so re distinct sources of danger to the community This nay perhaps seem a "large order" but it is to be remem ered that in the course of time, and probably in the course f a short time, provided that the adequate means are rovided for the treatment of early cases and that vigorous reventive measures are efficiently and thoroughly carried ut, the number of cases of phthisis (dangerous cases as they nay be termed) requiring such hospital accommodation will iminish and the cost to the community, which for the first ew years will be very great, will in the course of time ecome, comparatively speaking, small

But, further, it is, theoretically at least, the duty of the anitary authorities to see (so far as this is practicable and o far as such measures fall within the sphere of their action, out only in those cases in which the assistance of the nedical officer of health is demanded by the medical man n attendance) that the preventive measures (for the destruc ion of phthisical sputum) are carried out—in other words, to ee that the persons suffering from phthisis shall not be ources or danger and infection to the persons with whom hey are in immediate contact and to the community at arge. And this leads me to the next point, viz —

The special measures which the sanitary authorities should take in order to prevent the tubercle bacillus and its spores from being conveyed from one human being to another and from bovines to man.—We have seen that the two great sources of tubercle in the human subject are (1) the inhalation of dust containing the dried sputum from cases of phthisis, and (2) the introduction into the alimentary canal of food stuffs (more especially milk) containing the tubercle bacillus and its spores, and that if the prevalence of phthisis and other forms of tuberculous disease in the human subject is to be reduced to the lowest attainable limit measures must be taken to prevent the inhalation of tuberculous dust, and the introduction into the alimentary canal of tuberculous milk and (though this is much less important) of tuberculous meat. This being so, it is, I conceive the duty of the municipal and sanitary authorities and of the Government, if the assistance of the legislature is required, to take measures, so far as they are practicable, to prevent the tubercle bacillus or its spores from being conveyed (1) from one human being to another, and (2) from the lower animal—that is to say (practically speaking), from bovines to man

With the object of preventing the tubercle bacillus or its spores being conveyed from one human being to another the sanitary authorities should take the following measures 1. To instruct patients suffering from phthisis as to the necessity of destroying or disinfecting their sputum while it is still moist, as to the manner in which this should be done, and as to the danger which is entailed to the persons with whom they live and to the healthy members of the community by their expectorating on the floor, on the public streets, in workshops, public conveyances, &c 2. To provide, when they are required, the necessary appliances for the destruction and disinfection of the sputum 3 To see, so far as this is practical and so far as it falls within the power of action of the sanitary authorities, that any insanitary conditions which are present in the rooms, houses, and workshops in which phthisical patients live and work are removed. (This point has already been considered) 4 To disinfect, or cause to be disinfected, on the death or removal of a phthisical patient, the rooms and houses which there is reason to suppose are contaminated with the tubercle bacillus. I do not mean to imply that it is necessary to disinfect every room in which a phthisical patient has lived, or every room in which a phthisical patient has died, but only those rooms which there is good reason to suppose are contaminated with phthisical dust. I repeat that if our object is completely to eradicate and to stamp out phthisis and other forms of tuberculous disease sanitary measures of a general kind are insufficient and that special measures must be taken to destroy or to disinfect the sputum of cases of phthisis and other discharges which contain the tubercle bacillus Fortunately, there is no difficulty in destroying and disinfecting the sputum of cases of phthisis in individual instances provided that the nature of the disease is recognised, that the patient is properly instructed with regard to the destruction or disinfection of the sputum (or other discharges), and that these instructions are carried out. But, practically speaking, it is impossible with the means which are at present available to destroy and to disinfect the sputum in anything like the majority (it would perhaps be more correct to say except in a small minority) of cases of phthisis, for the disease is so persistent and so widely spread, it is so common, so much more common amongst the poor, ignorant, and careless members of the community, in whom the disease is often unrecognised in its earlier stages, since they do not in many instances seek medical advice until it is far advanced, and who, after the disease has been recognised, are in many instances either unable or unwilling to take the precautions which are necessary to prevent its extension to other people, and the individuals who are affected with phthisis and the houses in which they live are not known to the sanitary authorities There will, I suppose, be little or no difference of opinion that great advantages would result from the measures which have just been indicated (1, 2, 3, and 4) provided that the sanitary authorities were in a position to carry them into effect But without a compulsory system of notification the sanitary authorities are quite unable to carry them into effect The compulsory notification of phthisis is, in my opinion, necessary and essential if a serious and determined effort is to be made to reduce the prevalence of the disease to the lowest attainable limits (see Lectures IV and V) 5 Further, if phthisis and other forms of tuberculous disease are to be reduced to the lowest attainable limit it is, in my opinion, theoretically speaking, advisable (though some of these measures may at first sight seem to be arbitrary) that the sanitary authorities should insist so far as this is practicable, that the instructions which they issue regarding the destruction or disinfection of the sputum, attention to cleanliness, ventilation, and absence of overcrowding are carried out 6 They should also enact by-laws to prevent phthisical patients from expectorating in the public streets, in public conveyances, &c In New York and some other American cities this is, I understand, enforced, and in this country the sanitary authorities should, in my opinion, make by laws for the purpose 7 They should remove to hospital patients suffering from phthisis or other forms of tuberculous disease who, in consequence of the insanitary nature of their surroundings and their inability to take proper precautions, or their refusal to take proper precautions, to prevent the diffusion of the poison (the tubercle bacillus and its spores), may fairly be regarded as distinct sources of danger to the healthy persons with whom they are in contact and consequently to the community as a whole (This point has already been considered)

The measures which the municipal authorities, the local sanitary authorities, and the Government should take in order to prevent the tubercle bacillus and its spores from being conveyed from the lower animals, more especially bovines, to man—This is a large and important subject which I do not propose to discuss in detail Further, until Koch's view—that bovine tuberculosis is incommunicable to man, or very rarely, if ever, communicable to man by means of tuberculous milk and tuberculous meat—is definitely established or contradicted the detailed discussion of the restrictive measures, if any, which it is advisable and necessary to take in order to prevent bovine tuberculosis from being conveyed to man and in order to stamp out tuberculous disease in cattle is superfluous

---

HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK, N W —The annual meeting of the governors of this hospital will be held in the buildings of the new hospital, 4 Maida vale, on Wednesday, July 23rd, at 3 P M, when the Right Hon the Earl of Hardwicke, president of the hospital, will preside. The first section of the new hospital is now nearly completed and will contain 38 beds and all the necessary administrative accommodation for the complete building which will contain 60 beds A sum of £2500 is required to enable the committee to complete the fitting and furnishing of this part of the hospital, including the out-patient department

SOME RARE CASES OF SARCOMA OF THE THYROID[1]

BY P L. DANIEL, F R C S. ENG

DEMONSTRATOR OF PRACTICAL SURGERY (LATE SURGICAL REGISTRAR) TO CHARING CROSS HOSPITAL AND ASSISTANT SURGEON TO THE METROPOLITAN HOSPITAL.

THE subject of this paper might appear on superficial consideration to be rather of academic than of practical interest, but the subject of malignant disease in any shape and form is essentially practical and if by calling attention to it the early diagnosis of malignant disease of the thyroid will be facilitated and radical treatment thereby obtained a great amount of suffering and a terrible termination to life may be averted if permanent cure do not result.

Berry in his excellent work on the diseases of the thyroid body suggests that although sarcomata may appear to be equally common as carcinomata of the thyroid yet it is probable that more cases of sarcoma are recorded in literature or placed in museums on account of their greater rapidity of growth rendering them a more striking affection and that consequently carcinoma may be really the more frequent. In Charing Cross Hospital during the past six years we have on record one case of carcinoma, one of malignant adenoma, and four cases of sarcoma of the thyroid.

The four cases that I wish to record this evening confirm the statement that most cases of malignant thyroid are unfortunately seen at too late a stage for radical treatment. Extirpation was possible in one only and this case indicates clearly the uncertainty of diagnosis and prognosis and the difficulty of removing the disease once it has become extracapsular In one case tracheotomy was performed. Malignant disease of the thyroid is said to be more common in glands which have been the seats of previous non malignant growths This may be correct generally but there is no definite history in either of these cases to suggest the presence of any form of simple growth and in only one of the four cases was there a probability of any previous disease of the thyroid and this was not of the nature of a growth. In this case a preceding pathological condition may be assumed inasmuch as there is a possibility that the patient suffered to a slight extent from myxœdema for some time before the malignant disease was observed This however is a moot point as it is not improbable that a diffuse form of sarcoma may have existed for some time, resulting in the destruction of the essential elements of the thyroid and loss of function with myxœdema following as a logical sequence The disease generally affects males and females equally and the proportion is retained in this instance two of the patients being males and two females. It is more common in districts where goitre is endemic. During the later years of their lives these four patients lived at Barkfield in Kent, Lewisham Greenwich, and Wandsworth respectively none of which districts are, I believe goitrous. The onset of malignant disease of the thyroid is late in life Berry in his investigations limits practically its earliest appearance to 40 years of age. In these four cases the ages were respectively 57 59 60 and 69 years. The two younger patients were males, the two older were females. The patient who was 60 years of age had the symptoms of myxœdema and the one who was aged 69 years had the affected lobe extirpated The histological varieties of sarcoma found in the thyroid are either spindle or round-celled in three of the following cases the cells were round and of medium size. In the fourth the structure was that of a giant-celled sarcoma The duration of life in malignant thyroid is variable from nine weeks to two and a half years being the limits although in those cases grafted on to pre-existing simple growths the date of origin of malignancy is uncertain and its duration may be considerably longer These four cases terminated fatally in eight, nine, 12, and 17 months respectively from the period of earliest observation of the growth, and being primarily malignant the history is fairly accurate. The immediate cause of death in each case is recorded as follows The first patient died suddenly from heart and respiratory failure five or six hours after tracheotomy the second from syncope on the day upon which he was prepared for tracheotomy the third five days after extirpation, from exhaustion and the fourth from general suppurative peritonitis pleurisy and pericarditis The sarcomata grow more rapidly than do the carcinomata.

The seat of origin of sarcoma —Whether one lobe is more prone to involvement than the other I cannot say but the isthmus is the least frequent site of origin. Sarcoma generally is more prone to involve one lobe and to grow rapidly carcinoma early to involve the second lobe and to grow more slowly Of these four cases three were primarily in the right lobe of these one appeared in the mid line but was clinically and at the operation obviously a growth of the right lobe. In the fourth case the growth involved both lobes simultaneously but grew more rapidly in the right lobe so that in all four cases the right lobe appeared to be selected by preference. Involvement of lymphatic glands is variable and is too late to be of diagnostic value In three cases the cervical glands were involved and palpable but when they became the seat of new growth it is impossible to say In the fourth case—the (?) giant-cell sarcoma—no secondary glands were found.

Secondary growths —In the earliest case although the primary growth was most extensive and involved the walls of veins the fasciæ, and the pleura, no embolic deposits were found In the second case extensive secondary growths were found involving the dorsal and lumbar vertebræ, both kidneys both suprarenals the cœliac and cervical lymphatic glands and the stomach. The last will be referred to later In the extirpated case secondary growths were found in both kidneys and the cervical and thoracic glands were involved In the fourth case, that with co-existing myxœdema, there were malignant ulcers of the stomach and intestine malignant infiltration of the pancreas and the cervical glands were involved

Deviation of the trachea —In three of these cases deviation was not marked such slight deviation being the usual condition found in malignant disease The greatest was one inch In the fourth case—the (?) giant-cell sarcoma—the deviation of the trachea from the mid line was two inches Pain was not a prominent sign in either of these cases two patients complained of slight neuralgic pain situated in the neck and radiating up towards the ear and down towards the chest Dysphagia and dyspnœa were present in three cases

Ingrowth into the trachea —This is comparatively common and takes place usually from one half to an inch below the cricoid cartilage. In the second of these cases the larynx had been invaded and the mucous membrane was ulcerated. In the fourth (the myxœdematous) case there was distinct infiltration of the submucous tissue of the larynx and the trachea This extended for a distance of one and a half inches and resulted in a fusiform elevation , it extended above and below the cricoid and seemed to have enveloped, if not to have destroyed, the cartilage. There was no obvious loss of tissue—i.e. ulceration—over it

The consistence of sarcoma generally is softer than is that of carcinoma of the thyroid One of these cases was described as stonily hard one as firm and elastic, and the other two as hard.

Complete fixation of the mass to deep structures was found in three cases

The carotids —In two cases the carotids were embedded in the growth In the third case the vessel lay at the posterior border In the fourth case the vessel lay at the outer border below the growth

CASE 1.—The patient, a man aged 57 years who was admitted to hospital on Oct. 25th 1895 suffering from a tumour in the neck and was operated upon on the following day died suddenly on the day of operation The history of the case showed that during the winter of 1894 not more than 12 months previously the patient noticed a lump of the size of a small marble which was situated behind the right sterno-mastoid at the junction of the lower and middle thirds This disappeared in March, 1895 (at about the fifth month) and it returned in April since when it had gradually increased in size It had been painless and free from tenderness. In May (the seventh month) the patient began to have dysphagia for fluids there was no difficulty in swallowing solids In August (the tenth month) solids were taken with difficulty and this was accompanied by the onset of hoarseness. The dysphagia gradually increased the hoarseness remaining more or less the same Two weeks before admission the patient began to regurgitate food shortly after taking it, but he did not feel nausea. He had lost flesh during the last six months The patient had to recline or to sit up in bed, being prevented from lying down by a sense of threatened asphyxia. His expression was painful and distressed He coughed frequently The respirations, which were of a sighing, laboured character, were 28 and the rate of the pulse, which was small and weak, was 133. The patient was given two or three teaspoonfuls of beef tea which were disposed of with great effort About three minutes later, without difficulty or nausea, he regurgitated the beef tea unchanged This was repeated several times and on each successive occasion the beef tea became increasingly mixed with mucus The fifth time mucus composed the greater part of the regurgitated fluid and was markedly acid On examination the abdominal wall was found to be emaciated and retracted No tumour was felt and the liver was not enlarged Pulsation was felt along the whole course of the abdominal aorta. A large mass was seen on the right side of the neck, measuring *from four to five* inches vertically and from five to six inches transversely It extended from an inch to the left of the mid line in front to within two and a half inches of the mid-line *posteriorly* Above it reached as high as the base of the lower jaw, below it reached the clavicle and it projected about two inches above the normal surface of the neck. Numerous large veins ramified in the skin over the growth, but otherwise this was not obviously changed On palpation the skin was *found* to be not hotter over the tumour than elsewhere but it appeared to be markedly thin and more or less *adherent over the* growth. The mass was *absolutely fixed* to deep structures and was stonily hard in all parts There were no soft spots nor was fluctuation found *anywhere* The thyroid notch was felt two and a half inches *to the left* of the mid line, the trachea was consequently considerably deviated but was difficult to palpate (obscured by growth), and it appeared to lie near the mid line just above the supra sternal notch Mr Boyd decided on immediate tracheotomy and the operation was performed at 3 P M on Oct 26th A 5 per cent solution of cocaine was freely injected in all directions over the position of the trachea. *An incision* two and a half inches long was made from the lower *border* of the thyroid cartilage in a position two inches *to the left of the mid-line*, several bleeding points were secured, the *fascia* over the trachea was divided and the latter *exposed*, and three rings were cut A bi valve tracheotomy tube was *inserted* by means of a gum elastic catheter *used as a* stylet. The patient felt no pain, the injection of cocaine was repeated several times during the operation He was considerably relieved, the dyspnœa was markedly diminished, and he was comfortable. The patient died suddenly during the night from respiratory paralysis

---

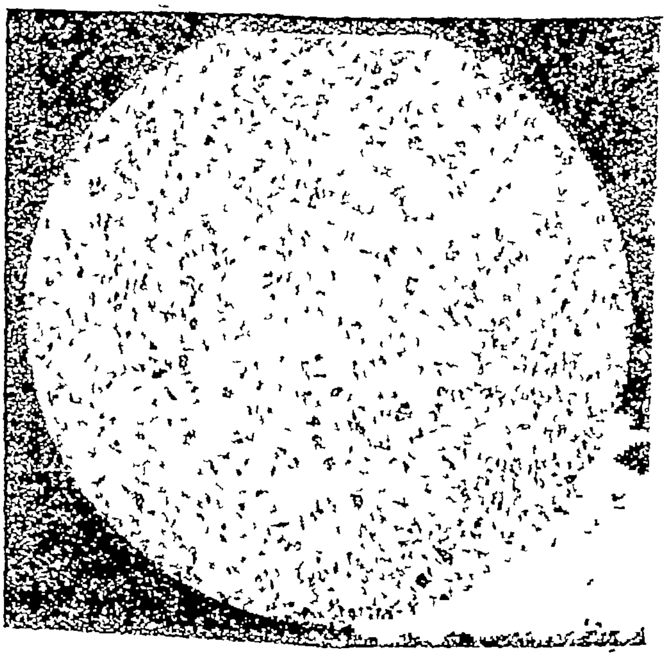
[1] A paper read before the Harveian Society of London on March 6th 1902.

At the *post-mortem* examination the patient was found to be sparsely developed and emaciated There was a large *growth* in the neck especially involving the right side, it weighed 15½ ounces The growth extended from the first rib upwards for five and a half inches, its depth below the first rib was four inches, its *breadth* was two inches, and its antero-posterior diameter was *three* inches It was lobulated, convex anteriorly *and* posteriorly where it was attached to the spine It blocked completely the right inlet of *the thorax* and was pale in colour, soft and brain like in consistence, and had the appearance of a sarcoma. It was firmly adherent to the anterior *aspect of* the lower cervical vertebræ behind the œsophagus It involved the right lobe and isthmus, extending well over to the left side of the trachea without implicating the left lobe of the thyroid The trachea had been greatly pushed over to the left side and in order to reach it the portion of growth in *front of* the trachea had to be cut through The growth was closely attached to the trachea The œsophagus lay between the tumour and the trachea, both the *œsophagus* and the pharynx were involved in the growth, especially the latter, the wall of which was *atrophied* The œsophagus must have been greatly pressed upon throughout the entire length of the growth Inferiorly the mass extended into the upper division of the thorax four inches below the level of the first rib It lay *in* concert with the apex of the lung but did not involve its substance. It involved the right subclavian vein in its course from the first rib to the innominate. It extended downwards over the arch of the aorta, involving the innominate and carotid vessels The left vagus was deeply embedded in the growth With regard to the heart there was no coarse lesion except one or two points of atheroma at the base of the aorta There was no other disease of the viscera The patient had an ununited fractured patella On looking at the cut surface of the growth a central circular area was seen which presented the appearance of carcinoma, while the greater portion of the periphery showed the solid homogeneous appearance of sarcoma.

The following are points of interest in the case

1. As to the histological appearances, sections showed under the low power an arrangement of cells which in parts immediately suggested sarcoma, there being little or no stroma and the cells were closely approximated and of fairly uniform size, but in other parts one would be led to diagnose carcinoma. Here there was a stroma consisting of degenerating fibrous tissue and round cells of a sarcomatous nature, throughout which were scattered, but not uniformly, a large number of what might be called giant cells (Fig 1), these were of irregular shape *and size*, and were *more or* less angular and showed evidence of nuclear proliferation, vacuolation, and cell inclusion (Fig 2) In a small minority only of the cells the nuclei were multiple and discrete (Fig 3), the majority presented imperfect nuclear proliferation Were these cells of that variety which is generally called giant cells of new formation? Or were they simply clusters of thyroid epithelium aggregated and compressed so that the protoplasm surrounding the nuclei appeared to form one mass? The great variety in size, shape, and distribution of the cells and the character of the nuclei suggested the latter possibility On the other hand, comparison with the imperfect giant cells of a growth removed by Mr Morgan from the subcutaneous tissue of the forearm of a youth in November, 1900, where no such epithelial cells could possibly exist, rendered it possible that they were not of thyroid origin Multi nucleated giant celled tumours growing in structures unassociated with bone have been recorded on numerous occasions Some of these have been described as carcinoma but the great majority as sarcoma Waring[2] has described a tumour which grew in the subcutaneous tissue of the neck which contained cartilage cells and showed cell inclusions but was probably, as he suggested, derived from some displaced embryonic osteo genetic tissue associated with the clavicle H Snow, Targett, and others have recorded giant celled tumours which have grown in the subcutaneous tissue

FIG 1.



Case 1 Low power Showing the giant cells interspersed in the fibrous and round-celled stroma

of the integuments and in the breast. I show a section of the growth removed by Mr Morgan also one of a giant-celled sarcoma recently removed by Mr Stanley Boyd from the breast of an elderly woman aged 60 years, *in which the giant cells show distinct multiple nuclei.* This patient (Case 1) was 57 years of age and most of Targett's cases were elderly subjects. He says that giant cells are seen in malignant tumours which have grown rapidly and are soft in structure. This thyroid tumour clinically was very hard but post mortem it was described as being *soft and brain like* It is probable that, as in the case of cysts, the hardness was due to tension and as the tumour was of rapid growth and Mr Boyd's "breast case" also showed recent very rapid increase in size Targett's statement is not negatived by these cases. Mr Morgan's patient was a youth At *the meeting of the Clinical Society of* London on Feb 28th, 1902, Mr G R. Turner showed giant-celled sarcoma growing from the synovial membrane of the ankle joint, and at the same time I had the opportunity of seeing a section from a case recorded by Mr Howard Marsh of a pedunculated sarcoma *growing from the under aspect of the patella. In both* these cases the cells were perfect myeloids but their origin is closely associated with bone forming tissues.

---

[2] Transactions of the Pathological Society of London, vol l

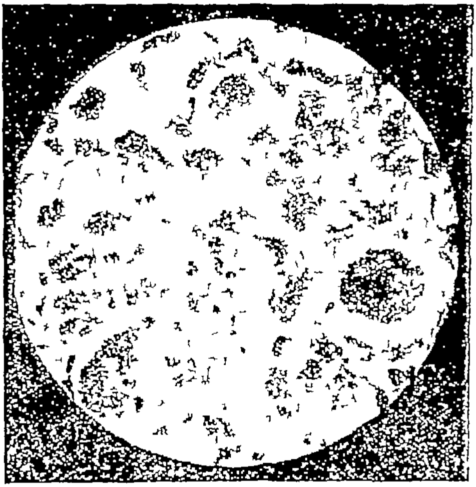
2. What was the cause of the dysphagia for fluids which set in first and which was not accompanied by signs of nerve involvement such as aphonia? The dysphagia for solids which occurred three months later was accompanied by hoarseness, showing probably direct involvement at the latter period of one recurrent laryngeal nerve Post mortem there was a note that the left vagus was deeply embedded in the growth, it was obvious from the specimen that the right *vagus and* recurrent laryngeal nerves were involved. It is possible that the early dysphagia for fluids was mechanical the fixation of the pharynx and larynx preventing the necessary movements, while the later dysphagia for solids was due to mechanical obstruction by pressure upon the œsophagus aided perhaps by paresis of the muscles due to increasing involvement of the vagi and recurrent laryngeal nerves. Or was the early dysphagia of nervous origin and the later of superadded mechanical origin? That this sequence is probable is shown by the fact that towards the end persistent and rapid regurgitation of both solid and fluid food occurred.

3. It is questionable whether the small tumour first seen and which disappeared for about a month was not an adenoma which moved about freely

CASE 2.—The patient, a married man aged 59 years, was admitted to hospital on Feb 28th 1898, and he died on March 10th. It was ascertained that a sister of the patient had died from cancer the site of which was not known. Eight months previously to admission the patient first noticed two hard lumps one on either side in the region of the thyroid lobes. He rubbed them with hartshorn and thought that for about three weeks they got smaller After this they began to increase in size the right side had always been bigger than the left. There had been only slight neuralgic pain in the neck The swelling on both sides had grown in a backward direction Since the onset of the swelling the patient noticed a considerable accumulation of mucus in the throat. During the last fortnight the growth became half as big again as it was before *On admission* the patient, who was a big powerful man, complained that he had lost flesh lately His breathing was very audible and tubular He could not swallow solids and his voice was slightly husky There was an enormous swelling in the neck occupying the right side, the centre, and to a less extent the left side, of the neck and extending *from the jaw to* the sternum. It involved both triangles The consistence of that portion of the swelling on the right side was uniformly elastic but it did not fluctuate Fixation to the adjacent parts was absolute. The skin on the right side was hot and congested but it was not tender or œdematous The skin on the front of the neck and on the left side was unaltered. Along the posterior border of the sterno-mastoid was a chain of enlarged glands. The left border of the mass corresponded to the posterior border of the left sterno-mastoid but the swelling on this side was far smaller than was that on the right side. Swallowing even of sops and fluids was difficult, but this varied In an ophthalmological examination by Dr W C Bosanquet nothing pathological was found. Laryngological examination was carried out by Dr F Willcocks The patient did not elevate his epiglottis in phonation, there was much swelling of the epiglottis and the arytenoids. The vocal cords were not visible. The superior orifice of the larynx was compressed laterally Mr Morgan did not consider the patient sufficiently distressed to need tracheotomy for some time after admission. Dyspnœa and dysphagia increasing however the patient was prepared for operation but he died suddenly from syncope

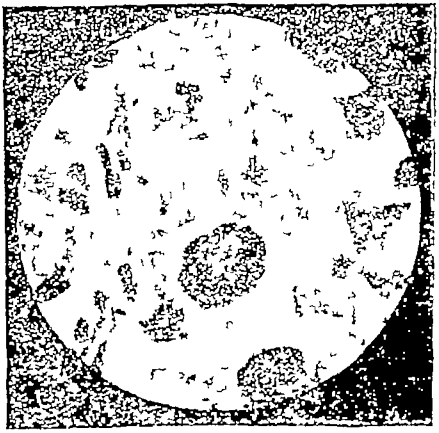
That tracheotomy should be delayed *until the dyspnœa* has become a source of considerable distress to the patient is the teaching of those who have had experience of these cases, *as* once the incision is made septic changes in the

FIG 2.



Case 1 High power Showing a giant cell with vacuolation and *cell inclusion*

FIG 3.



Case 1 High power Showing a giant cell with nuclei arranged circumferentially

growth and the complications following tracheotomy are very prone to occur Palliative operations such as partial excision for relief of pressure symptoms should be undertaken only when there is great probability that the skin incision will completely heal or when the symptoms of distress are great. Tracheotomy may be performed early when there is danger of œdema of the glottis occurring or when the growth is slow and the tumour can be avoided in reaching the trachea. (*Vide* Semon's case)

At the post-mortem examination the left pupil was seen to be larger than the right. The neck, which was greatly thickened by growth, was 21 inches in circumference The growth was adherent to the skin on the right side, it extended up under the angle of the jaw and was firmly adherent to the cervical fascia. On the left side the line of cervical glands, much enlarged, could be distinguished separately The thyroid growth involved the isthmus and both lobes The right lobe and isthmus could not be distinguished as such, the left lobe on section retained its shape, though it was much enlarged There was slight ulceration of the laryngeal mucous membrane The growth did not extend into the mediastinum and the glands in the thorax were normal. There was no pressure on the veins The left carotid, with the nerves, was embedded in its sheath, in the growth near the bifurcation the vagus nerve was tightly involved and compressed The right carotid was lost in the growth In the lower dorsal region a large secondary growth springing from the vertebræ projected forwards and partly surrounded, without involving, the aorta. It extended between the laminæ backwards and several secondary nodules were found in the muscles behind The spinal cord was not affected although the growth was very near it There was a large mass of growth in the glands behind the cardiac end of the stomach, this was adherent to, and growing through, the stomach wall near its cardiac orifice and was fungating in the cavity The growth involved half the circumference of the wall of the stomach near the cardiac orifice, part of it had ulcerated and it presented a hæmorrhagic appearance About the middle of the stomach was a small ulcer with raised firm margins of the size of a sixpenny piece Both kidneys contained new growths The largest, which weighed eight and a half ounces, was in the left kidney, that in the right weighed seven and a half ounces Both suprarenals were involved by solitary growths, the largest occupying the whole of the left capsule The liver and spleen were congested but there were no new growths The lungs were not diseased

The points of greatest interest in the case are the following 1. The association of ulceration of the stomach and intestine in sarcoma of the thyroid in this case and in Case 4 The condition of the stomach I will refer to in discussing Case 4 2. The signs of hyperæmia and the post-mortem evidence of attachment to the skin show how closely the latter may be involved and yet resist perforation It is possible that the heat and redness of the skin might be due to involvement of the sympathetic, as suggested by Agnew, the rapid increase in size, however, towards the end, suggests that some inflammatory reaction was set up The increase certainly was not due to hæmorrhage or to cystic degeneration Clinically no note was made of eye changes, yet probably such existed, as an ophthalmological examination was made and the left pupil post mortem was stated to be more dilated than the right, probably the left sympathetic was becoming involved 3 The secondary growths were exceedingly large and numerous, they were also median or symmetrical Rolleston states that the vascular medulla of the suprarenals is more often affected by secondary deposits of sarcoma than of carcinoma

Were the lumps first noticed simple growths irritated by the vigorous application of hartshorn and undergoing sarcomatous change in consequence? This is extremely improbable. On the other hand, spontaneous disappearance of malignant growths has been not infrequently noticed and in Case 1 also we have the statement that the first growth seemed to disappear Thyroid sarcomata have shown great decrease in size following tracheotomy The very notable case recorded by Sir Felix Semon[3] and that recorded by Mr G R Turner[4] are cases in point

CASE 3.—The patient, a widow, aged 69 years, who was admitted to hospital for swelling of the neck on Feb 1st, 1900 was operated upon on the 3rd Death took place on the 8th. The patient had had no children and had been a widow for four years She had suffered from chronic bronchitis Nine months previously her attention was drawn to the swelling by a shooting pain extending into the top of the left breast and up to the right side of the neck into her ear The swelling was in the mid-line of the neck low down and had extended upwards gradually It had grown more rapidly during the last few months The swelling itself was painless For some time she had had a "funny" sore throat and complained that it hurt her to swallow her spittle but not food She did not complain of unusual dyspnœa but obviously her breathing was not easy and natural even while she was at rest On admission the patient was found to be a fairly healthy looking woman for her age and had a good colour but was rather thin. The urine contained a little albumin. Occupying the lower part of the neck and extending from the sternal notch below, upwards to the level of the thyroid notch in the mid line was an oval swelling of the size of a goose's egg It lay obliquely and occupied chiefly the right side but it extended well beyond the mid line into the left anterior triangle The skin and veins over it appeared to be normal On palpation the swelling was found to have a smooth surface except at its upper right lateral angle, here it terminated in a blunt point like the lateral lobe of the thyroid On this were small masses, probably enlarged glands which caused it to be irregular at this part (? glands pushed into prominence) The growth did not appear to affect the isthmus and the left lobe was normal. In consistence it was firm and elastic, like a deep-seated thick walled cyst. The right sterno mastoid was stretched over the swelling but the inner edge of the muscle stood up clearly on bringing it into action The infrahyoid muscles could not be demonstrated. The trachea was pushed towards the left side from three quarters of an inch to an inch beyond the mid line The right carotid artery was pushed backwards into the posterior triangle and could be easily felt pulsating behind the sterno mastoid The growth was not freely moveable but did not give the impression of being very fixed to surrounding parts, but it was firmly fixed to the trachea and moved with it on deglutition The larynx was normal and the cords moved perfectly, the voice was unaltered The patient did not complain of dyspnœa but she certainly breathed rapidly and with obvious effort Dysphagia was not present except when the patient wished to swallow her spittle. She had coughed considerably since admission but she attributed this to chronic bronchitis There was not much expectoration. Under the anæsthetic Mr Stanley Boyd revised his diagnosis thus "The evidence of deep cyst is very doubtful. Against malignancy is the smooth circumscribed surface and outline, the absence of dysphagia and of interference with the recurrent laryngeal nerve. In favour of malignancy is the short history, the patient's age, the fixation to the trachea, and the prominence of glands at the upper angle " Yet after Kocher's angular incision was made and the growth bared it appeared "as a pale, slightly bossy, circumscribed, encapsuled mass, it looked like an adenoma and I endeavoured to enucleate it, but could find no inner capsule of thyroid tissue so determined to extirpate it." Great difficulty was experienced in removing the growth which extended deeply into the thorax. A continuous chain of glands was seen Into the cavity which was left in the thorax after the removal of the growth air was being freely sucked. A doubtful nodule of growth was observed in the cut surface of the portion of isthmus left The wound was drained. The prognosis was grave. After the operation the patient was in a very precarious condition Next day surgical emphysema developed and the patient appeared almost comatose unti she was given a brisk purge (on the assumption that the condition was uræmic), which entirely dissipated the symptoms. She did not pick up at all after the operation and died on the fifth day

I think the interest in this case lies in the following points 1 The deceptive clinical appearance and signs The growth appeared to be encapsuled, oval in shape, and i consistence it appeared even to such an experienced surgeo as Mr Stanley Boyd to suggest the probability of a deep seated thick walled cyst and it was moveable on deglut tion The carotid artery, instead of being overlapped an surrounded, as is usually the case in malignant thyroids, wa pushed backwards and could be felt easily at the posterio border of the growth The patient appeared to be in goo general health and her signs and symptoms might all b attributed to chronic bronchitis Under the anæsthetic a revision of the diagnosis was made, yet after incision the growth on its anterior aspect showed a pale, slightly bossy circumscribed and encapsuled tumour It appeared to have traversed its capsule on the posterior aspect which is probably accounted for by the fascial arrangements. That malignant growths of the thyroid tend to extend backwards in a marked manner has been clearly indicated by the cases which I have seen. The extreme difficulty with which the growth was removed shows how great may be the fixation to surrounding parts and yet allow up-and-down movement with deglutition. I should personally in future lay more stress on lateral movement with the trachea. 2. The drowsiness noticed after operation was similar to the condition in the case recorded by Mr G R. Turner previously referred to, in which after the operation the patient was comatose until a brisk purgative had acted. This patient was albuminuric likewise. 3. The surgical emphysema. 4 It is interesting to note that in Case 2 both suprarenals and kidneys and in this case both kidneys were symmetrically involved in secondary growths.

[4] Transactions of the Clinical Society of London 1890

CASE 4 —The patient, a married woman, 60 years of age, was admitted to hospital on April 24th 1901 for tumour in the neck. She died on May 14th—the twentieth day The urine had a specific gravity of 1015 was acid but contained no albumin or sugar The patient had suffered from bronchitis every winter and she also had asthma. There was no history of goitre, of cancer or of myxœdema She had been treated for dyspepsia and constipation during the past 12 or 15 months. In October 1899—that is 17 months before admission—the tumour was first noticed it appeared to have commenced on the left side in the position of the left lobe of the thyroid. It then seemed to involve the right side and had increased greatest on the right side The husband of the patient said that when the fulness of the throat was first noticed the patient's skin began to be very dry and she developed progressive weakness Her speech was always slow and she was rather stout but not to the extent now observed. The consistence of the swelling was not noticed. Six months previously the right side began to increase rapidly in size and the growth steadily persisted It was accompanied by an increase in stoutness. She was seen at this time by Dr G H. Charlesworth of Wandsworth who at once diagnosed myxœdema. When she was admitted on April 24th 1901, the neck looked very thick—that is, it was broad, full and expressionless there were no elevations or depressions visible. This fulness was most marked on the right side. On palpation a large tumour was found to occupy the neck which was more prominent on the right than on the left side. It obscured the trachea and was hard and solid and had distinctly defined margins, but the fulness of the neck extended beyond these margins. The carotid on the right side seemed to lie posteriorly and deep to the swelling On the left side it was palpable at the outer border The skin was free from attachment and except for a dark pigmentation where the patient had been painted and blistered with iodine it seemed normal The mass was adherent to the deep parts and was very fixed It did not move on deglutition The trachea was deflected a little to the left but palpation was difficult. It could be felt in the mid line below The thyroid cartilage was easily felt in the mid line but was not visible, being obscured by fulness The lymph glands were enlarged and of firm consistence and were easily felt on the left side but less easily on the right side above the level of the growth. The patient had the characteristic appearance of myxœdema—i.e. subcutaneous thickening double chin puffy eyes, and swollen hands. She was slow of comprehension and speech the latter was drawled. All her movements were slow the voice was peculiarly harsh, thick, and of deep tone. The skin was dry harsh, and coarse. Her hair was scanty but the scalp was uniformly covered. She was placid if left alone but was easily irritated. It was said that her voice had become harsher during the previous six months and that her breathing had become shorter she complained of the latter considerably but there was no obvious dyspnœa when she was at rest. Her temperature on admission was about normal During the night she had some dyspnœa. She was put on Burroughs and Wellcome's thyroid tabloids which were gradually increased to five or more tabloids a day She was being kept under observation to see the result of thyroid feeding and was considered to be inoperable. On April 28th her breathing had been variable in frequency and ease. She had considerable expectoration and so was given an expectorant mixture Her temperature was 98° F On the 29th the cough was worse. She was more cyanosed complained of difficulty in drawing her breath, and was much less comfortable. The pulse was rapid and feeble and she had some sibilant rhonchi. On the 30th after a distressed restless night she complained of pain in her throat of a shooting character and was given chloral When seen on May 6th it was ascertained that the patient had felt and shown no ill effects of the thyroid extract. There was less œdema of the fingers and hands, the nose was less swollen the face had improved and the speech was clearer and more rapid The dyspnœa, on the whole, was getting worse and especially affected her at night, so she slept badly There was little or no cyanosis The pain in the throat occurred now and again The cough was variable. Examination of the larynx revealed no evidence of paralysis of the vocal cords and the breathing was not stridulous. The expectoration was less and the temperature continued about normal On the 9th the dyspnœa was still well marked. The patient was restless and she felt more comfortable when lying on her right side. Speech and intellect were better the puffiness about the eyes was less, the face was thinner and more natural and the neck was probably slightly smaller especially about the left lobe. On the 11th—the seventeenth day after admission—suddenly without obvious cause and without a rigor the temperature rose to 102° and subsequently to 104° The patient had slight diarrhœa, the dyspnœa became well marked, and the skin pallid. She felt very ill but could not say how She completely lost her appetite and although considerable improvement had been made as regards the myxœdema she rapidly got worse. The thyroid extract was discontinued. The temperature continued at 104° and then gradually fell. The pulse became thin and feeble ranging from 130 to 160 Slight delirium developed at night. A marked shrinking occurred in the size of the tumour The neck became quite slim and except for a localised swelling on the right side the growth seemed to disappear She occasionally complained of pain in the abdomen and always persisted in lying on her right side, slightly propped up. She did not vomit and after the first day of fever her bowels did not act. Her condition for the last three days of life may be summed up as follows. The temperature was 104° falling to 101°, there were intense restlessness, marked dyspnœa with pallor and cyanosis a thin thready pulse varying from 130 to 160 and slight pain in the abdomen there was no vomiting she was constipated she was conscious but was too distressed to speak much about herself and at night she became a little delirious most of the subcutaneous thickening and the thyroid fulness seemed to disappear suddenly there was no suspicion of pelvic trouble and no signs of secondary growths were observed. She died on the twentieth day after admission.

Post-mortem examination showed the right lobe of the thyroid to be involved in a mass of new growth but the left lobe appeared to be normal. The trachea was narrowed by the growth and was pushed to the left side. The growth extended above to beyond the hyoid bone and below to within one and a half inches of the bifurcation of the trachea and measured four inches vertically Anteriorly the isthmus was thickened and was continuous with the new growth in the right lobe The right carotid and jugular were almost completely surrounded by new growth at the postero-external angle the vein lying external. The bifurcation of the common carotid was involved in new growth The subclavian could be separated from the growth but the lower end of the carotid was very adherent. The right half of the cricoid cartilage was embedded in new growth which had extended into the submucous tissue forming an elevation of a fusiform shape one and a half inches in extent reaching above and below the level of the cricoid. There was no evidence of ulceration over the swelling The growth lay in a retro-tracheal position, extending from the level of the tip of the epiglottis to the subclavian artery The larynx was compressed from the right side and behind The left lobe was firm and looked very fibrous there was a mass of pigmented glands at the bifurcation of the trachea, and considerable tracheitis was present. Examination of the thorax showed purulent pleurisy on the right side and serous pleurisy with flakes of lymph on the left side. In the cavity of the pericardium there were flakes of lymph. The heart was normal. The lungs were compressed but were otherwise normal. The cavity of the abdomen was full of greenish yellow turbid purulent fluid.

The stomach —An ulcer twice the size of a florin lay near the cardiac orifice of the stomach and near it were two smaller recent ulcers with raised thickened edges There was no thickening of the wall of the organ Near the pyloric end was another recent ulcer of the size of a sixpenny piece, also two large chronic shallow ulcers, one of the size of a five-shilling piece

Intestines —Two or three small sharply cut ulcers existed in the middle of the ileum The mucous membrane of the lower part of the small intestine was stippled with dark dots throughout. In the neighbourhood of the cæcum and throughout the colon the mucous membrane was almost black with closely set points of pigment The ureters contained much muco purulent fluid In the Fallopian tubes was a small amount of pus The kidneys were slightly granular The spleen was normal The mucosa of the intestine examined microscopically showed masses of brownish pigment deposited between the glands, there were no hæmatoidin or hæmatin crystals Microscopically the pancreas showed infiltration by new growth

The points of interest in the case are (1) the direct association of myxœdema with sarcoma of the thyroid and (2) the ulceration of the stomach and intestine The most interesting feature is the association of myxœdema with sarcoma of the thyroid

Quoting Dr G R. Murray,[5] "in only a few exceptional cases has the destructive lesion of the thyroid gland been traced to a definite cause Kohler describes two cases, one of syphilis and the other of actinomycosis of the thyroid Neudorfor gives one case of adenoma of the right lobe of the thyroid. In each of the three cases appropriate treatment of the exciting cause was followed by recovery of the functional activity of the thyroid gland and disappearance of the myxœdema." Assuming that Dr Murray has collected all the cases bearing on this subject this case appears to be an exceptional one.

It is impossible to state whether the myxœdema, of which clinically there is no doubt, was due to sclerosis or to senile atrophy of the gland antecedent to the malignant change, or whether a diffuse sarcomatous infiltration was the immediate cause of the glandular destruction and consequently of the myxœdema. The history states definitely that the development of the symptoms of myœdema, with one exception, that of slow speech, was coincident with an enlargement of the thyroid which became slowly progressive When a marked increase in the size of the thyroid took place six months before death the symptoms of myxœdema also became more pronounced. Senile atrophy as a cause of myxœdema is rare Clinically it was observed that thyroid treatment seemed to result in diminution in size of the left lobe. This may be best explained by assuming disappearance of the mucinoid deposit in the tissues about the thyroid, as microscopically there is no evidence of regular gland structure in any of the sections of the left lobe which I have examined, everywhere there is the diffuse infiltration with round cells, here and there may be seen remains of thyroid epithelium identical with the condition of the right lobe

The condition of the stomach —In this case marked ulceration of the stomach and slight ulceration of the small intestine with pigmentation of the latter were found. In Case 2, besides the massive involvement of the cardiac extremity of the stomach by the secondary growth in the cœliac glands, there was separate ulceration of the stomach near the pyloric extremity similar to that in Case 4 In a case not yet recorded of probably primary sarcoma of the larynx with bilateral growths in the thyroid there was found similar ulceration and new growth in the stomach This association of ulceration of the stomach with thyroid sarcoma may be a coincidence but there are many points in favour of a direct relationship Primary and secondary sarcoma of the stomach may be of four varieties (1) round-celled, (2) spindle celled, (3) myosarcoma, and (4) angeiosarcoma Primary growths are much more common than are secondary ones except in the lympho sarcomatous variety in which *secondary* involvement of the stomach is more common than is *primary* deposit (Hemmeter) and is most often found secondary to primary growths involving the neck, the pharynx, the gums, &c Primary growths tend to be nodular and begin in the submucosa Ulceration of the mucous membrane is late and signs and symptoms may be entirely absent, the post-mortem examination revealing the presence of growth for the first time

In the two cases now recorded what is the nature of these ulcers? In Case 2 the nature of the large ulcer was indubitable—viz, that of an ulcerating sarcoma The smaller ulcer presented the same macroscopical characteristics as those in Case 4 and the small ulcer of the laryngeal case referred to The latter is microscopically undoubtedly sarcomatous, so we may assume that the nature of the ulcers in Cases 2 and 4 is similar Macroscopically those in Case 4 appear to be of two varieties, one having the appearance of acute ulcer, the other chronic with thickened edges There was slight thickening with increased vascularity at the base of some of the ulcers but not of all Microscopically the more acute ulcers showed a condition of erosion of mucous membrane surrounded by round celled infiltration in the mucosa and submucosa impossible to distinguish from an inflammatory process The area of ulceration appeared to be more vascular than did other portions of the stomach walls If the brownish flocculent fungating portion of the new growth projecting into the stomach in Case 2 be brushed off the ulcer left is identical in appearance with the small ones seen in Cases 2 and 4 Probably at one time these had fungating growth adherent to their surface The patient in Case 4 was for some time under treatment for dyspepsia and constipation, but her symptoms were not marked and there was no obtainable history of hæmatemesis The duration of her symptoms seemed to have been coincident with the thyroid troubles. Extensive ulceration of the stomach may occur with few symptoms, yet it might be assumed from the condition of pigmentation of the intestine in this case, if due to blood absorption, that considerable hæmorrhage from the stomach had occurred from time to time, but the history did not support the assumption. Also the pigmentation was absent in the upper jejunum and was least marked in the lower jejunum and the upper ileum and most pronounced in the lower ileum and the colon It is reasonable to assume that a great deal of the blood came from the intestinal ulcers, situated half-way down, one of which had probably ulcerated deeply and eventually perforated, causing general peritonitis.

The origin of the ulcers —In Case 4 from the appearance and situation of the primary growth it is obvious that the pharyngeal muscles were involved by the new growth at their origin from the cricoid. In Case 2, from the extensive nature of the growth, a similar conclusion must be deduced. The larynx also was *ulcerated* slightly In the unrecorded case of primary sarcoma of the larynx with ulceration of the stomach referred to the explanation which I beg to give of the origin of these ulcers suggests itself—namely, that it is probable that some of the sarcoma cells were swallowed and passing through the mucous membrane of the stomach and the intestine gave rise to secondary submucous growths. In my cases the pharyngeal mucous membrane need not have been perforated to permit this as cells of at least equal size constantly escape in the process of inflammation and probably under normal conditions also between the epithelium of mucous membranes In addition in Case 4 there was involvement of the larynx which might be a possible source of sarcoma cells Thursfield[6] recorded a case of primary sarcoma of the stomach in which the infiltration was diffuse and ulceration was not present In this case there was a mass in the region of the parotid and left thyroid Was the stomach growth primary? The association of secondary lympho sarcomatous growth in the stomach with primary lesions of the gums, the pharynx, and the neck, recorded on repeated occasions, suggests that some such simple explanation as I have suggested is probable.

In conclusion I will quote Kocher and Berry

> Kocher ' Every goitre in an adult and especially in an elderly person that enlarges without obvious cause should raise a suspicion of malignancy, even though it should cause no pain or other trouble. If at the same time the goitre becomes harder and irregular and symptoms of increasing distress set in then the diagnosis becomes almost certain The prognosis as regards malignant goitre from the operating point of view is not worse than that of innocent goitre if performed while the growth is intracapsular When the growth is still intracapsular there are no means by means of which we can make a certain diagnosis of malignant disease "
>
> Berry "When however in the thyroid gland of a person over 40, a tumour appears which is hard, which steadily and rapidly increases in size and which is not of an inflammatory nature the malignancy of such a tumour should be strongly suspected If moreover the surface of the tumour is irregular and bossy and if there is likewise dysphagia and pain in the neck shooting up to the side of the head or to the shoulders, then the diagnosis becomes almost a certainty

My thanks are due to Mr Morgan and to Mr Stanley Boyd for permission to record these cases to Dr Bosanquet for much assistance and advice, and not least to Dr Hunter for great assistance and permission to utilise the perfectly mounted specimens of the cases

Devonshire-street, W

ON THE

ACETONE SERIES OF PRODUCTS IN CONNEXION WITH DIABETIC COMA

BY F W PAVY M D LOND LL.D GLASG F R.S.
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

(Continued from p 66)

THERE are two views of the pathogeny of diabetic coma which stand in a position to claim consideration The one refers it to an acidosis or excessive production of acid and the other to the β-amidobutyric acid, an assumed precursor of the β-oxybutyric acid

Excessive proteid disintegration is attended with excessive acid production. The sulphur and phosphorus of the proteid becoming oxidised give rise correspondingly to sulphuric and phosphoric acids. Under natural circumstances these acids encounter a sufficiency of fixed bases to neutralise them but when developed in excess they have to attach themselves to a portion of the ammonia at the same time developed by the proteid disintegration and in this state they pass into the urine. Normally the amount of ammonia in the urine is very small, inasmuch as what is developed by downwards metabolism combines with the carbonic acid at the same time being produced and the combination becomes transmuted into urea. Combined with sulphuric or phosphoric acid the ammonia cannot pass into urea but escapes as the unaltered compound. Thus from simple increased tissue breaking down a source exists for the undue presence of ammonia in the urine and when the breaking down is attended with the formation of the additional acids oxybutyric and diacetic, that have been receiving consideration ammonia is appropriated and carried off by them into the urine, and thus the amount may rise from something under one gramme per diem to six or seven grammes or even more. The quantity of these acids that may be formed is such as to constitute a factor from more than one point of view of much significance. Estimations of diacetic acid are not given, for no satisfactory method of estimating it exists but it must be reckoned that whatever diacetic acid is present means an addition to the troubled state otherwise induced. As regards oxybutyric acid it is not uncommon for from 50 to 70 grammes per diem to be eliminated It is accepted that as much as 150 grammes per diem may be eliminated and considerably higher figures than these have been named (e.g 226 grammes—approximately half a pound—by Külz) but doubt of the correctness of the extreme figures that have been given may be entertained From the records supplied cases have occurred in which the oxybutyric acid has exceeded in amount the sugar The waste occurring in these circumstances must be something enormous. The elimination of oxybutyric and diacetic acids constitutes an outgoing of material carrying with it unexpended energy and the same applies to the sugar Hence with all three an immense sacrifice of potential energy is occurring

Acidosis is the term which has been applied to the state resulting from the production of these acids. As they reach the blood they must obviously tend to decrease its alkalinity The available fixed alkali, as already stated is first appropriated for neutralisation and when the supply of fixed alkali fails the effete ammonia from proteid disintegration is taken and accompanies the acid into the urine. Notwithstanding these sources for neutralisation it has been found in cases when coma has supervened that the alkalinity of the blood has become reduced to a point standing much below the normal.

In the circumstances mentioned we have a sequence of events holding it may be considered a thoroughly established position. The existence of such a source of acidity cannot do otherwise than by its influence on the constitution of the blood, act deleteriously The altered constitution of the blood due as in the "alimentary" type of diabetes to the presence of sugar unaccompanied with any other condition interferes with nutrition and recognisably damages the kidney Experience shows that where sugar is allowed to be passing for a long time through the system a certain amount of albumin appears in the urine and granular and hyaline casts become discoverable. This condition may go on for a long time in, as it were, a quiescent form and without any of the classical phenomena of Bright's disease becoming developed although sometimes whether incidentally or derivatively well marked Bright's disease with the concomitants belonging to the granular kidney type of it becomes established. When the acidosis state is added to the other kidney damage, indicated by moderate albuminuria with granular and hyaline casts, may with greater certainty and rapidity be looked for Indeed, if marked acidosis exists I think it may be said that albumin and casts may be expected to be found in the urine

I now come to the pathogeny of diabetic coma, and as I have said there are two views to which attention will be given. These are autotoxicosis from acidosis and from β amidobutyric acid.

As far back as 1877 it was found by Walter[1] that when hydrochloric or phosphoric acid was given in repeated full doses to rabbits a state comparable to that existing in diabetic coma was induced The heart's action became much increased in frequency the breathing forced deep and more frequent, like what is appropriately termed the "air hunger" breathing of diabetic coma and the animal passed into a stupefied state. It was noted also that the carbonic acid in the blood dropped from about 24 to 2 5 and 3 per cent. a condition that has since been found to agree with that observable in connexion with diabetic coma. Further when the rabbit was on the point of death in coma the injection of carbonate of soda restored it. At the time when these experiments were performed the acidosis associated with diabetes had not been recognised but from its suggested existence it was looked for[2] and in the course of a few years the presence of oxybutyric acid[3] was discovered It was in this way that the acidosis associated with diabetes was worked out and whether it supplies the true explanation of diabetic coma or not it is found that with the supervention of coma the acids are present in the blood in such quantity as to be not far remote from covering its alkalinity With this condition, as in the experimental acidosis, the amount of carbonic acid in the blood drops. Figures as low as 3 3 per cent. were noted by Minkowski[4] in a case during the existence of coma Three weeks previously in the same case they stood at 17 per cent. For comparison he mentions quoting from the work of another authority that 30 6 per cent. may be given as a representation of the normal amount present in arterial blood of the human subject.

By the advocates of the acidosis theory as an explanation of the production of diabetic coma it is considered that when the acids developed begin to fail to meet with bases to neutralise them a condition is reached productive of coma The effect of the administration of carbonated alkali in the circumstances agrees with that observed in experimentally induced acidosis and soda has been frequently employed as a measure of treatment with, in some cases temporary restoration from coma Instances of the kind stand on record but the final issue has been disappointing The bicarbonate of soda is the preparation that has been used and very large doses have been found necessary to be given, so large, indeed as to create a difficulty in putting the treatment into force. Magnus Levy[5] relates a case in which a boy aged 13 years, was twice brought out of coma by the administration of 200 grammes (a little over seven ounces) of the bicarbonate of soda. In another case recorded by Magnus-Levy[6] the patient a girl aged 12 years recovered from fully-developed coma under the administration of 100 grammes per diem and showed no further signs of coma during the nine weeks she subsequently remained in hospital. Notwithstanding however that success may be thus for a while obtained in the end coma supervenes which fails to be any longer susceptible of removal[7] This is not to be wondered at looking at the circumstances actually existing It is true that, besides the neutralising action which is the main purpose of the treatment, the elimination of oxybutyric acid is greatly increased, but the production of the acid which constitutes the real fault to be dealt with remains untouched

Writers speak of the altered constitution of the blood by the reduction of its alkalinity as the cause of the coma connected with acidosis and refer the result to the effect of the altered condition of the blood on the tissues of the body This, however, amounts only to an assertion which gives no insight into the actual pathogeny of the coma. If we bring the mind to bear upon the matter an explanation becomes opened out which carries us to the depths of physiological action and shows the precise *modus operandi* in relation to the question. In effect the acidosis state, if looked into, is seen to offer an impediment to the performance of an indispensable functional operation connected with the vital activity of the tissues—I mean the removal of the carbonic acid developed in them as an attendant phenomenon of life. By the train of reasoning to be brought forward we arrive at finality in connexion with the matter

The blood, as we know, conveys oxygen to, and carbonic acid from, the tissues It is in the tissues that oxidation on the one hand and production of carbonic acid on the other takes place, the process constituting what is termed the "internal respiration" The oxygen is conveyed in loose combination with hæmoglobin and is taken by, and embodied in, the living protoplasm where in reality the chemical interactions of life occur The oxygen thus embodied does not, it is considered, directly unite with carbon and hydrogen to form carbonic acid and water but as a part of the combination into which it has entered participates in a succession of changes of degradation presumably taking place and resulting in the formation of carbonic acid and water as main final products. The carbonic acid formed requires to be carried away and it is chiefly by the agency of the carbonate of soda in the blood that this is effected Brought into contact with carbonic acid the carbonate of soda becomes converted into bicarbonate The bicarbonate thus formed is conveyed by the blood to the lungs where it yields up its intake of carbonic acid to the air and returns to the state of carbonate which starts again on another round of work. Thus it is seen that the carbonated alkali of the blood performs in relation to carbonic acid a transport service similar to that which hæmoglobin performs in relation to oxygen. A limited amount of carbonic acid is also transported in simple solution In the cold blooded animal, where, on account of lower vital activity, the production of carbonic acid takes place on a much smaller scale, this mode of transit may suffice to accomplish what is wanted, as is evidenced by the continuance of life in a frog for a considerable number of hours when a saline solution has been substituted for its blood. In the warm blooded animal, however the production of carbonic acid is such that the capacity of transport by simple solution sinks to insignificance looked at in relation to the total quantity required to be conveyed, and the further provision supplied by the carbonated alkali is indispensable Hence the effect of the loss of alkalinity of the blood is to deprive it of its power of carrying away the carbonic acid formed in the tissues If the carbonic acid, the production of which is an essential phenomenon of vital activity, cannot be carried away it must obviously accumulate in the tissues and the only result that can be conceived sooner or later to follow is arrest of vital action. Choked with the product of their activity the tissues must yield to its toxic influence. Viewed in this way death intelligibly becomes a necessary consequence of the loss of the alkalinity of the blood With the advance of the acidosis a period will be reached when, under the reasoning adopted, a fatal termination must ensue

The characteristic breathing in diabetic coma testifies to the defect existing in connexion with the function of gaseous exchange To the condition the term "air-hunger" has been applied and it certainly looks as if efforts were being made to rectify a deficiency of air in the system. The inspirations are deep and prolonged and although more air than can be obtained seems to be wanted there is nothing to reveal any obstacle to the entry of air into the chest It is in the tissues that the respiratory want supplies the stimulus that regulates the mechanism of respiration. The lungs serve for the exchange of gases between the blood and the air, whilst the blood serves for the transport between the tissues and the lungs of the gases to be exchanged. For efficient tissue respiration these portions of the respiratory mechanism must be in a fit state for performing their work. Anything which interferes with the proper passage of oxygen to, or of carbonic acid from, the tissues will derange the chemistry of tissue life If oxygen fails to reach the tissues in sufficient quantity or carbonic acid adequately to be carried away the result in each case is that the chemical operations of life are checked and functional power diminishes till a state of coma ending in death is produced. In acidosis the fault lies with the defect in the carrying power of the blood for carbonic acid by the loss of its alkalinity As a consequence the tissues become poisoned by the carbonic acid that fails to be carried away A corresponding defect in the carrying power of the blood for oxygen is occasioned by carbonic oxide This gas, reaching the corpuscles, combines so tenaciously with their hæmoglobin as to prevent the subsequent ingress of oxygen The tissues are in this way prevented from obtaining their supply of oxygen just as they are prevented from getting rid of their carbonic acid under the existence of acidosis A parallelism, it is thus seen, in relation to defective transport action exists in the two cases

The outcome of what has preceded is that the retention of carbonic acid in the tissues is the cause of diabetic coma with its associated "air hunger" character of breathing The phenomena observed agree with the effects of carbonic acid poisoning occasioned in other ways The acids in the blood which writers upon the subject of acidosis speak of as producing, through their alteration of the constitution of the blood, the toxic results stand in the position of the precursory and not the immediate factor In the condition produced by privation of oxygen there is, as might be expected, a similar train of phenomena. There is this distinguishing feature, however, that while convulsions occur in connexion with the coma of oxygen deprivation they are absent in carbonic acid poisoning [8]

I previously said that there were two views bearing on the pathogeny of diabetic coma to which attention would be given. The view that remains to be considered is that of Sternberg,[9] which refers the coma to the toxic action of an assumed antecedent of oxybutyric acid—viz., amidobutyric acid Proceeding upon the presumption that diabetic coma is due to a toxic agent in the blood and assuming that oxybutyric acid is derived from the disintegration of proteid he thought that an amido compound of it would be a likely precursor This led him to experiment upon the effects of the series of amidobutyric acids upon the system, and in doing so he found that the β amido acid acted toxically and produced symptoms resembling those of diabetic coma There is first, he says, an excitement stage and next the comatose stage with deep and slow breathing Grube[10] has repeated his experiments and obtained corroborative results I notice that Sternberg speaks of the heart being strong and slow in action, but rapidity of action is one of the associations of diabetic coma. According to his suggestion the amidobutyric acid is a transitory step in the degradation of proteid towards acetone, and by delay of transition a toxic result may occur Its presence in the body is only hypothetical, but with reference to this it is said that it passes with too much rapidity into the lower forms of the series for it to be recognisable.

On account of its seeming feasibility this amidobutyric acid theory has met with widespread favourable consideration. Forcible objection, however, has recently been raised to it Magnus Levy[11] gives an illustration showing that on the presumption of amidobutyric acid constituting a precursor of oxybutyric acid the quantity of the latter eliminated much exceeded what was compatible with the nitrogen elimination that occurred The trend of opinion also at the present day from the recent evidence that has come into our possession is to the conclusion that oxybutyric acid is not actually derived from proteid, and if this is the case there is no ground for assuming that the production of an amido compound enters into the series of changes occurring There is likewise against the amidobutyric acid theory the collateral consideration that with the occurrence of carbonic acid poisoning *as a necessary sequence of acidosis* nothing more is wanted. When acidosis is looked at simply as acidosis exerting a toxic influence on the tissues it is permissible for some other condition to claim an equal pretension to consideration but looked at, as has herein been done, from the point of view of interfering with the performance of a necessary physiological operation, anything further becomes unneedful.

---

[8] Since this section was written I have met with remarks by Bunge ("Physiological Chemistry" translated by Starling 1902) which coincide with the view that has been submitted Without entering into any particulars he simply says that acids reaching the blood deprive it of its carrying power for carbonic acid which thence accumulates in the tissues and by its toxicity is the source of the coma of diabetes

(*To be continued.*)

THE TREATMENT OF INTRA PERITONEAL ABSCESS OF THE APPENDIX.

BY F. C. WALLIS F.R.C.S. ENG.

ASSISTANT SURGEON TO CHARING CROSS HOSPITAL; SURGEON TO THE METROPOLITAN HOSPITAL, ETC.

IN the accompanying small series of consecutive cases of abscess of the appendix it will be noticed that in every case except the last the abscess was intra peritoneal—by which is meant that the abscess which is formed in connexion with the appendix, although shut off by surrounding adherent coils of intestine, was in no way adherent to the parietes or only so slightly as to form no protection. In every case, therefore, the general peritoneal cavity had to be opened before the abscess could be dealt with.

The following are details which were performed in each case. A comparatively small incision is made through the skin down to the rectus sheath which is divided. The length of the initial incision depends mainly upon the thickness of the abdominal parietes. The rectus muscle being pulled inwards the posterior part of its sheath is opened and the peritoneum is incised and held apart by forceps. If now the finger is introduced and a search more or less roughly carried out for whatever may be found the consequences will be disastrous the abscess cavity will almost inevitably be opened and the contained pus escape into the general peritoneal cavity Great care is necessary to avoid this catastrophe as *in the young* even after many days the *adhesions are of the frailest character* and unless the intestines are manipulated with gentle hands these adhesions give way and expose the general peritoneal cavity to the infection of the escaping pus To avoid this, when the peritoneum has been incised a blunt hook with a large curve is used to pull up the parietes on the left side of the incision. The general peritoneal cavity is shut off all round by introducing pieces of Gamgee tissue about from one and a half inches to two inches wide above internally and below, thus forming a crescent around the affected area. Now the abscess may be looked for by gently separating the adhesions in the neighbourhood of the appendix. This must be done *quite* gently otherwise the pus, which is always under a certain amount of tension may escape too rapidly to be controlled. If this does occur as it sometimes will in spite of all proper care, the patient should be immediately tilted over to the right side and the pus directed to a small bowl held underneath. When the pus escapes gently it can be sponged up as it wells out of the cavity until the tension has ceased when the opening is separated more widely and the cavity is thoroughly cleansed by sponging with Gamgee tissue (marine sponges should not be used) If there is any appendix to be removed this should be done now, the cavity is then dusted with iodoform and filled with iodoform gauze. In one or two cases the cavity was swabbed out with pure carbolic acid but the subsequent oozing was so excessive that I gave it up. It is important especially for the first 24 hours, to keep the surroundings as dry as possible and iodoform powder with moderately light packing of the gauze answers well. This packing is removed on the fourth day—i.e. after the bowels have acted—as a rule. In some of the cases peroxide of hydrogen was used to clean up the abscess cavity I have used it now for some years and can recommend it. The abdominal incision is closed by one set of interrupted fishing gut sutures, care being taken that each layer of the parietes is picked up by the needle—a large curved Hagedorn—as each suture is passed

It will be noticed that seven out of the eight patients were young—a matter I believe of some considerable clinical importance. It is not intended in this paper which is only a record of one's clinical experience, to deal with the vast amount of literature on the subject, but from what I have read and from what I have gathered from the clinical experience of others—and it certainly is my own—suppurative appendicitis is much more common in young people than the recurrent form and hitherto sufficient importance has not been attached to this fact. In all these cases the attack which ended in suppuration was the primary one. The onset in each case was a sharp, definite attack of abdominal pain, and in most cases this—perhaps naturally enough—had been looked upon as an ordinary stomach ache by the patient or relatives, and the sufferer had continued to go about for several days before applying for medical relief. Herein lies the danger If by chance adhesions form—and fortunately this is the rule—before the pus escapes from the appendix a bulwark of safety has been made which is of great value. But many of us have had personal experience of those cases when a young life is lost in two or three days by a suppurating appendix bursting before any sufficient adhesions were formed.

Another point which I have already mentioned is the *frail* character of the surrounding adhesions in the young even after many days Case 1 was operated on 10 days and Case 4 four days, after the original attack yet in each case as in all the others save one, quite delicate manipulation was necessary to avoid bursting the adhesions before the necessary guards had been placed around the affected area. The importance of recognising this clinical fact is evident. The one exception to this was Case 7 The age of the patient in this case was 48 years and here the adhesions were firm and strong forming a good protection In my experience this also is the rule in patients about this age These facts emphasise the necessity of operating quite early after the primary attack of appendicitis in young children. In all these cases a thorough view of the abscess cavity was obtained and whenever any appendix or portion of it remained this was removed at the time. When the pus tracked up behind the colon a posterior incision was made from which the wound drained and the anterior incision was closed

The sequel of commencing intestinal obstruction which occurred in Case 5 shows the advisability of removing any omentum which may owing to its inflammatory condition be capable of contracting adhesions with neighbouring coils of intestine. A certain amount was removed in this case but, as the sequel shows, not enough The rapid convalescence which ensued in all these cases was, I believe due in great measure to the thorough cleansing of the abscess cavity at the operation and to the removal of whatever was left of the appendix

With regard to the somewhat vexed question as to whether the appendix should or should not be removed at the time when the abscess is opened I do not think that any hard and fast rule can be made. In four of my cases the appendix was seen when the abscess cavity was exposed and was comparatively easily removed. But any systematic search when the appendix was not apparent was not made and I do not think that it would be good surgery to make one, as very serious harm might be done by opening up the peritoneal cavity and recurrences after an abscess has formed when the appendix has not been removed are rare

The treatment of the last case on the list is one which I have adopted lately when pus or puriform fluid was found in the general peritoneal cavity but at the time there was no general peritonitis My reason for such treatment is my great and growing respect for the wonderful protective and recuperative power of the peritoneum when not irritated by chemical solutions and rough manipulation which in these cases do nothing but harm.

CASE 1.—The patient, aged 15 years was admitted into Charing Cross Hospital on July 6th 1900 Operation was performed on the 13th and the patient was discharged on August 12th. There was pain in the abdomen on July 3rd, when castor-oil was given, and sickness on the 4th and 5th. The temperature varied from 101° F at night to 98 6 in the morning The patient was transferred to the surgical side on the 13th when, as stated above, the operation was performed. The abdomen was somewhat distended. There was slight respiratory movement and the abdomen was markedly tender especially over the right iliac region where the skin was slightly œdematous and a distinct fulness could be made out. At the operation the skin was incised for two inches over McBurney's point the rectus sheath was opened and the muscle was pulled inwards When the peritoneum was opened thickened œdematous omentum presented itself and the incision was enlarged one and a half inches In the mid line was a mass of omentum, underneath which was a gangrenous appendix and a small quantity of very offensive pus The appendix was removed, the abscess cavity was swabbed out, and a portion of thickened omentum was cut away The cavity was dusted with iodoform powder and was packed with iodoform gauze, and the greater part of the incision was brought together with silkworm gut sutures The iodoform gauze was removed three days after operation and a small piece was reinserted into the cavity for drainage purposes The cavity filled rapidly and the patient was discharged on August 12th. The patient was again operated upon on Jan 25th, 1901, for small ventral hernia.

CASE 2.—The patient, a girl, aged 13 years, was admitted into the Metropolitan Hospital on Oct 11th, 1900 Operation was performed on the 16th and she was discharged on Nov 13th The patient had been taken suddenly with abdominal pain on Oct 2nd. She kept about until the 7th when she went to bed and diarrhœa commenced. She was admitted into the hospital as suffering from enteric fever When she was seen after admission a definite swelling in the right iliac fossa was discovered and appendicitis was diagnosed. At the operation an abscess was found situated between the adherent small intestines and cæcum This was treated in the manner described above An uninterrupted recovery followed Peroxide of hydrogen was used as a lotion.

CASE 3—The patient, a girl, aged 15 years, was admitted into Sutton Cottage Hospital on Sept 4th, 1900 Operation was performed on the 9th and the patient was discharged on Oct. 9th She had been taken ill with abdominal pains and vomiting on Sept 2nd, the pain and resistance were most marked in the right iliac fossa. When she was seen on the 9th there was a well-marked swelling in the right iliac fossa, the temperature being 103 2° F, but the patient was lying on the affected side reading a book. At the operation an abscess was found containing nearly one ounce of characteristic pus This was treated on the same lines as the others The patient made an uninterrupted recovery

CASE 4—The patient, a youth, aged 17 years, was admitted into the Metropolitan Hospital on Feb 6th, 1900 Operation was performed on the 23rd and the patient was discharged on April 3rd He had been seized with acute pain in the lower abdomen during the night of Jan. 30th and this was followed by vomiting The pain and daily vomiting continued until his admission into the hospital, when an indefinite swelling was found in the right iliac fossa extending as far as the middle line This swelling was dull on percussion At the operation the omentum, which presented through the wound, was found adherent to the anterior abdominal wound and also to a loop of small intestine, this loop was adherent to the lower part of the cæcum Between these coils was a small abscess and the remains of the appendix These were removed and the cavity was packed with gauze The patient made a good recovery, but the sinus was longer than usual in filling up Peroxide of oxygen was used as a lotion

CASE 5—The patient, a youth, aged 17 years, was admitted into Charing Cross Hospital on Oct 26th, 1900 An operation was performed on the 26th and he was discharged on Jan. 9th, 1901 The previous history of this patient was not clearly made out, but on admission he was quite ill and had obvious signs of suppurating appendicitis At the operation the omentum, the small intestines, and the cæcum were all matted together, and on separating these a considerable abscess cavity was exposed filled with foul pus In the cavity was the gangrenous appendix, this was removed and the cavity was swabbed out and packed with iodoform gauze A portion of the sodden and thickened omentum was removed. The patient did very well until the third week, when he had symptoms of intestinal obstruction, necessitating a laparotomy, which was performed in the mid line, when two coils of intestine were found adherent to the great omentum. These were separated and the patient made a good recovery

CASE 6—The patient a girl, aged 11 years, was admitted into the Metropolitan Hospital on July 1st, 1901 Operation was performed on the 2nd and she was discharged on August 4th. She had first complained of pain in the right iliac fossa on June 25th, which gradually became worse until the 29th. There had been no sickness The bowels had been opened twice a day On the day of her admission into the hospital she had lamb and mint-sauce twice At this time her temperature was 103° F and her pulse was 132. The abdomen had a distinct fulness and sense of resistance in the right iliac and lumbar regions, where manipulation caused pain On opening the abdomen the colon presented itself This was pulled towards the middle line and an abscess cavity situated externally to the colon was found, which held two ounces of foul pus The cavity extended up towards the liver and was lined with a thick white membrane A posterior incision for better drainage was made in the loin and the abscess cavity was treated in the same way as the other cases Recovery was uninterrupted

CASE 7—The patient, a female, aged 48 years, was admitted into the Metropolitan Hospital on July 3rd, 1900 Operation was performed on the 4th and the patient was discharged on August 14th She had suffered from sudden severe pain in the lower abdomen on June 25th which settled in the right side, there was no sickness but rather violent retching The abdomen moved freely on respiration and on palpation a large mass could be felt in the right iliac and lumbar regions which extended upwards to the lower surface of the liver The abdomen was opened by an incision four and a half inches in length When the transversalis muscle was reached it was found to be much infiltrated and thickened On opening the abscess cavity firm adhesions formed definite and safe boundaries (the only case of this series where this was so) The abscess cavity was treated in the usual manner Recovery was uninterrupted

CASE 8—The patient a young man, aged 20 years, was admitted into the Metropolitan Hospital on Nov 5th, 1901 Operation was performed on the same day and the patient was discharged on Jan 4th, 1902 He had suffered from a sudden attack of pain with shivering and nausea on Nov 3rd, 1901, since when the bowels had not acted and no flatus had been passed Vomiting commenced on the 5th. On admission the patient looked very ill. The temperature was 97 5° F and the pulse was 120 The abdomen was distended and rigid, it did not move with respiration and was very tender all over the right iliac fossa. The feet and hands were found to be peeling in a manner suggestive of scarlet fever When the patient was sent into the hospital the case was notified as one of typhoid fever On the abdomen being opened the intestines in the right iliac fossa were found to be covered with a thin puriform fluid There were no signs of adhesion or appearance of localisation of peritonitis A long, swollen appendix was found lying on the outer side of the cæcum, between it and the parietal peritoneum This was removed and a quantity of sero purulent fluid was withdrawn by a syringe from the right side of the pelvis The wound was treated as in the other cases, with the addition that a large drainage tube was passed down into the recto-vesical pouch The patient was constantly sick until Nov 8th when, after repeated treatment, the bowels acted well. Recovery after this was uninterrupted When on the 15th the stitches were removed it was found that no union had taken place, the whole wound gaping and exposing the intestines No ill effects followed this unusual *contretemps*

Harley-street W

INTUSSUSCEPTION OF A DIVERTICULUM WITH SECONDARY ILEO-COLIC INTUSSUSCEPTION

BY FRED T TRAVERS, B S LOND, F R C S EDIN,
SURGEON TO THE WEST KENT GENERAL HOSPITAL, MAIDSTONE.

ON April 3rd I was asked to see a boy, 10 years of age, who was suffering from sickness and abdominal pain He had been quite well until the previous day, when he sat down with the rest of the family to breakfast. Suddenly, before taking any food, he complained of abdominal pain and vomited The vomiting had continued at frequent intervals up to the time of my seeing him, that is, at 6 30 P M next day There had been a good action of the bowels on the 1st and no recent constipation or diarrhœa, neither flatus, mucus, nor blood had been passed since this action The child was lying with his legs drawn up, his face was flushed, and his tongue was dry and brown The pulse rate was 116 and the temperature was 98° F He complained of pain in the right side of the abdomen. On examination the abdomen was seen to be flat, with the exception of a slight but distinct prominence on the right side. In the area thus defined a *tumour* could be felt, about two inches in length by an inch in width lying with its long axis at right angles to the middle-third of a line from the umbilicus to the right anterior superior spine of the ilium. It was firm and tender and dull to percussion. Nothing else abnormal could be felt though the abdominal wall was quite yielding. A rectal examination gave no information. There had been only slight tenesmus but an attempt to defecate just before I saw him had caused much pain and had increased the vomiting. The sudden onset of the illness and the symptoms of obstruction, with the condition of the patient, strongly pointed to an intussusception. The early and persistent vomiting and the position of the tumour suggested the ileum as the part affected. I therefore directed his friends to take him at once to the West Kent Hospital at Maidstone, his father being a labourer with a large family. At 9 P.M. I *saw him in the hospital. The* swelling in his abdomen previously noticed had entirely disappeared but now a somewhat indefinite mass could be felt in the position of the ascending colon. His pulse-rate was 132 and he had been again very sick. Operation was decided upon and at 9.30 P.M. I opened the abdomen by an oblique incision two and half inches in length parallel to the fibres of the external oblique muscle and one and a half inches from the iliac spine. The external oblique was split and the deeper layers were drawn aside and slightly notched. On opening the peritoneum the cæcum presented. It was quite flaccid and empty. This and the long vermiform appendix were rapidly examined. The ascending colon was then felt and was found to contain a doughy mass extending for three and a half inches and with a hard lump of the size of a filbert at its apex. The ileum was hooked up with the finger and was found to be intussuscepted into the colon. By gently pressing down the mass in the colon the ileo-cæcal valve was first everted from its position three-quarters of an inch from the base of the tumour. The ileum appeared to go directly to the harder portion mentioned and by carefully pushing this down and drawing out the ileum some three inches of gut and then this mass were reduced. The passage of this portion through the ileo cæcal valve was effected by pushing it through from the distal side and was the only part which gave any trouble. As soon as it was free a number of small coils of bowel easily followed which had been packed in closely and which came out much as string comes from the inside of a ball. Finally, the returning layer formed by the last three inches of the ileum was reduced. This portion of bowel showed signs of having been greatly distended and the peritoneum was sutured in two places where there were lacerations. The adjoining part of the ileum, 14 inches in length, was on reduction much compressed and anæmic but in a very few minutes it resumed a normal appearance. Above this 18 inches from the valve, was the swollen part. On examining this it was found that a pouch or diverticulum was here intussuscepted or rather inverted into the bowel forming a polypoid mass which almost completely obstructed the lumen of the gut. This was partially replaced but owing to the swelling of its coats could not be entirely reduced, its apex still remaining tucked in though it no longer projected within the bowel. The diverticulum about three-quarters of an inch in length and nearly of the size of the little finger sprang from the gut opposite to its mesenteric attachment. A point, however which drew my attention was the presence of a fold nearly half an inch wide running from the mesentery around the lower surface of the bowel to the little diverticulum, the edge of the fold being free and forming a little recess above and below in the angles between the ileum and the pouch. The bowel was replaced and the wound was closed, buried sutures uniting the out muscular walls. The operation lasted just half an hour, the patient rallied well from the ordeal and the sickness ceased entirely. The bowels acted on the 5th after a small enema. The tongue, though moist continued to exhibit a thick fur until after the administration of several 10-grain doses of sulphate of magnesia on the 6th. The stitches were removed on the 13th and the boy was sitting up in bed on the 18th and he returned to his home on May 2nd.

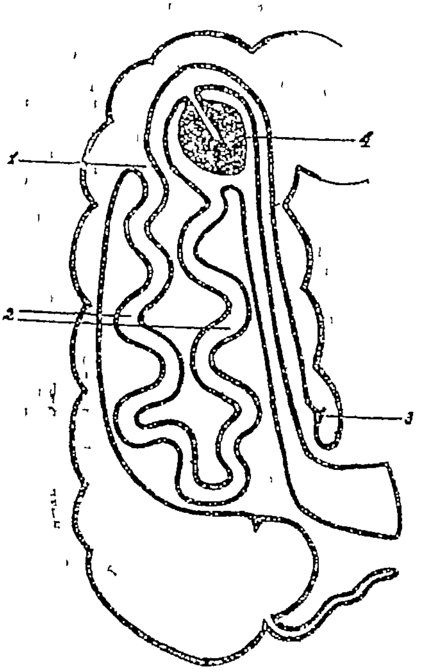

Diagram illustrating intussusception due to an inverted diverticulum. 1, True apex of the intussusception. 2, Ileum 14 inches, in tightly packed coils. 3, Position of the ileo-cæcal valve. 4, Inverted diverticulum showing œdematous thickening of the walls.

The condition here appears to have been primarily due to inversion of the diverticulum which then formed a polypoid mass and induced irregular peristalsis and secondary intussusception. The œdematous state of this pouch and the bowel wall immediately adjoining it showed that it had been affected longest, indeed at this point alone was there any œdema present. The secondary intussusception was I think when first seen still of the simple enteric form and the tumour then felt was altogether on the proximal side of the ileo-cæcal valve. The change of position and shaking consequent on the removal of the patient produced the condition found at the operation, the enteric intussusception having become ileo-cæcal. The difference in the conditions of the abdomen at 6.30 P.M. and at 9 P.M. was very striking. The stretched appearance of the returning layer of the ileum and the injury to its peritoneal coat can readily be accounted for—although from the absence of œdema or circulatory disturbance the part cannot have been long involved—by the fact that into between three or three and a half inches of inverted ileum some 18 inches of the adjoining bowel and the mass formed by the inverted diverticulum had been tightly packed. The coils of bowel were wedged in by the latter which had been carried right up to the apex of the tumour.

The total absence of the classical symptom of the passage of blood and mucus is noteworthy and the almost complete freedom from tenesmus exemplifies well how dependent this is on the implication of the large bowel in the affection which here apparently occurred quite late.

The diagram gives almost exactly the arrangement of the bowel in the tumour, the tightly packed coils of bowel being partly omitted for the sake of clearness.

Maidstone.

THE WATER-SUPPLY OF NEWPORT (MON.).—At the monthly meeting of the Newport corporation held on July 8th it was reported that the supply of water in the reservoir was less by 14,000,000 gallons than for the corresponding period of last year. The service has been suspended during several hours each night for over 12 months and the shrinkage now going on foreshadows a very severe situation at the end of the summer.

A CASE OF VERTICAL OR COMPLEX HERMAPHRODITISM WITH PYOMETRA AND PYOSALPINX, REMOVAL OF THE PYOSALPINX.

By E. PERCY PATON, M.S. Lond., F.R.C.S. Eng.,
ASSISTANT SURGEON TO WESTMINSTER HOSPITAL, ETC.

THE case of which the notes are given below is, I think, of sufficient general interest to be put on record.

A patient, aged 20 years, came under my care at the Mildmay Mission Hospital, Bethnal Green, on March 17th, 1902. He was complaining of very frequent and painful micturition and thickness of the urine and some tenderness over the bladder. On examination he was found to be a double cryptorchid and to be hypospadiac, the hypospadias being of the perineal variety; the penis was very poorly developed and only between two and three inches long, there was a depression in the glans at the normal seat of the meatus, but this opening was blind, and the whole of the floor of the penile urethra was wanting, the urine being discharged by an opening in the perineum which admitted a No. 10 catheter with ease. On either side of this opening were two folds of skin representing the split scrotum, but the folds were empty, there being no signs of testes to be found here or in either inguinal region. Extensive scarring was to be seen on the right side of the hypogastric region which the patient said was due to an abscess which had been opened about a year before and which had now been closed for about six months. Beneath this scar there was to be felt an ill defined fulness the nature of which could not be clearly made out, partly on account of its tenderness and partly because of the scarring. The condition of the urine varied a good deal at different times; sometimes there was a very considerable amount of pus present; at others he would pass a very fair quantity which was almost clear—occasionally, but only on one or two occasions, and not at any regular intervals, there was a little blood present. On passing a catheter it was never possible to obtain more than a small quantity of urine at one time and this was always thick with pus, though he could often pass six or eight ounces at once himself when the quantity of pus was usually much less. In general appearance the patient was very small and puny for his age. He had no hair on his face and the pubic hair was scanty; his face had rather a feminine aspect, his voice was also high pitched. The breasts were more developed than is usual in a male, the development being similar to that usually seen in a girl about 15 years of age.

An investigation of his history showed that he had always been a rather feeble person and that he had been for the most part of his life at an orphan school owing to the early death of his father, but the authorities there had not noticed anything peculiar about him except his physical deformity and general want of development. There was no evidence to be obtained of menstruation. His mother also said that his brother and sister, who had emigrated to Canada, were both well developed. He had been earning his living as a tie maker for the last three years except when he had been laid up with the abscess mentioned above and with an attack of bronchitis. He did not appear to show any special sexual feeling, but had been always considered a male.

He was at first treated by having the cavity into which the catheter passed, and which was thought to be the bladder, washed out daily and this diminished the hypogastric tenderness and the amount of pus in the urine. But as a thorough examination could not be made he was given an anæsthetic on April 7th, a large fluctuating tumour was then found in the hypogastrium which appeared to be the bladder but the catheter failed to draw off more than a small quantity of urine and left the swelling as it was. Rectal examination enabled one to feel this swelling bimanually and also to feel a mass which felt like an elongated prostate on its posterior surface but this extended above the reach of the finger and its connexions could not be clearly made out. Under the scar there was also to be felt a much smaller mass, but this could not be properly defined as it was masked by the larger swelling.

Three days later the patient was again anæsthetised with a view to opening his abdomen. It was then found that the state of parts was quite altered as the large fluctuating swelling was absent and only the smaller one to the left of it could be felt. An incision was made in the middle line and the abdomen was opened below the umbilicus. On separating a good many adhesions there was found a tube-like structure, running up from the pelvis to be adherent to the old scar and also to a coil of gut, and on more clearly defining this it appeared to be a Fallopian tube full of fluid and of about the size of the middle finger attached along the upper border of a very rudimentary broad ligament and leading at its inner end to what appeared to be a uterus which, though not fully developed, was of considerable size and to which was attached on the other side another Fallopian tube which seemed to be normal. To the posterior aspect of the left broad ligament there was found attached a gland which was of the size and appearance of a normal ovary. The large cystic swelling which had previously been felt was found to be the bladder considerably dilated but now empty. The left tube and the gland were now removed; no similar gland was found on the right side, but no very careful examination could be made as the operation had lasted for some time and it was thought well to close the abdomen. The recovery from the operation was uninterrupted but pus continued to be passed in the urine although the general condition was much improved. On May 8th as the discharge of pus still continued, a further careful examination was made, the intention being, if thought advisable, to scrape the interior of the uterus after dilatation of the hypospadiac opening; it was found, however, that to do this it would be necessary to slit up the orifice considerably, and as it seemed improbable that it would heal kindly, and as if it did not it would seriously inconvenience his micturition, it was thought well not to do this at present but to continue the treatment by irrigation. It was found that a uterine probe could be passed for four inches with ease and clearly did not go into the cavity which at the previous operation had been identified as the bladder; a very careful and prolonged attempt to get a small metal catheter into the bladder was not successful.

The patient is now in very good general health and has gone out of the hospital, but is being kept under observation and is having the uterine cavity occasionally washed out, it being intended if the discharge continues at some future date to remove the rest of the appendages.

The examination of the parts removed gave the following results. The tube had in every respect the ordinary structure of a Fallopian tube, somewhat dilated so as to contain about a drachm of pus, in which no organisms were demonstrated by ordinary staining or by staining for tubercle bacilli. The gland showed in one part a structure which there could be no doubt was that of a rudimentary testis, as ill-formed tubules could be very clearly seen; in another part of the section there was a mass of cells of which the nature was uncertain. These cells varied in shape, being mostly cubical and round cells and some short spindles, but there were none like ovarian cells; possibly they were derived from the original cells of the germinal epithelium.

Remarks.—In this case the following seems to be the condition of the sexual organs. Externally the penis was small but otherwise normal except for the fact that the urethra had no floor. What appeared to be the opening of the urethra was really the opening of a very rudimentary vagina into which the uterus opened by a fair sized aperture and the urethra by a very small one; the folds on either side of the opening in the perineum might be taken to be either rudimentary scrotum or labia. Internally there were a very fairly well formed uterus and tubes, and on the left side the gland which was removed was clearly a testis; it was uncertain if there was a similar gland on the right side. There was no evidence of the existence of epididymis, vas deferens, or prostate, but it was quite possible that these might be present in a rudimentary form as no examination to settle this point could of course be made. The bladder was normal save for considerable increase in size. The general build of the individual was rather of the female than of the male type. The above mentioned points would lead one to classify the case according to Simpson's classification[1] as one of true double, vertical, or complex hermaphroditism, in which part of the internal organs are of the male and part of the female type, though some deny the term true hermaphrodite to any case in which both an ovary and a testis are not present.

SIX CASES OF MENINGITIS IN ONE HOUSE, WITH TWO DEATHS

BY EDWARD H. SWEET B A. OXON M R.C.S. ENG L.R.C.P LOND.

THE following cases, all of which occurred within a period of two months present many points of difference from the text-book descriptions of either cerebro-spinal or posterior basic meningitis.

At the beginning of this year the occupants of the house wherein the cases occurred consisted of the father the mother, the mother's sister and nine children (eight boys and one girl) varying in age from 11 years to twins born in December last. One of the twins died in January last from broncho-pneumonia. As regards the family history of this household the father had tuberculous disease of one lung the mother was not strong but had no disease her sister was a strong and healthy woman, and another sister had died some years ago from consumption. The parents of both the father and the mother were alive and in good health and the family history was otherwise a very good one. In February of this year the whole family suffered from influenza, followed by troublesome coughs

CASE 1.—Early in April last the girl, aged six years complained of a stiff neck and constant headache. She was occasionally sick and quite lost her appetite. I saw her first on April 28th and found her very much thinner than when I had attended her two months previously for influenza. She was drowsy sick after every meal, and complained of a dull pain all over her head. Constipation was very troublesome but the tongue was not at all coated. The pulse was soft and irregular and the temperature was 99 2° F Knowing the father's condition I feared tuberculous meningitis. The sickness easily yielded to careful feeding and ordinary stomachics but the constipation continued to be troublesome all through her illness in spite of two-grain doses of calomel twice a day As soon as the sickness stopped I administered three grains of iodide of potassium with five grains of bromide of potassium every four hours in addition to the calomel. The stiffness of the neck had decreased and was not much complained of at this time. At no time was there any retraction of the head, irritability or photophobia. As a rule the patient lay curled up in bed with the eyes half closed and had no objection to being moved. Emaciation progressed rather rapidly though liquid food was well taken and retained and the abdomen became much retracted. Tache cérébrale was well marked. On May 1st I examined the eyes. The pupils were slightly dilated and they reacted sluggishly to light. The discs were swollen and retinal hæmorrhages were present in both eyes. There was never any screaming convulsions were absent and there was no squint. The patient gradually sank into insensibility, and on May 12th she died. During the last three days the temperature rose to and remained at, 101° The pulse continued to be irregular and was generally about 100.

CASE 2.—Before I saw the child in Case 1 the eldest boy aged 11 years, had been brought to me with a history of constant headache, occasional vomiting loss of appetite restlessness, and grinding of the teeth at night The bowels were very constipated but the tongue was fairly clean. The sickness appeared to be quite independent of food and it came on quite suddenly I suspected worms and treated him for them without any result. He remained under treatment for six weeks and is now quite well.

CASE 3.—On May 28th I was asked to see the mother and I found her suffering from constant sickness and severe headache—chiefly occipital. The bowels were very constipated, the pulse was irregular and weak, and the temperature was 96° F I prescribed three grains of calomel and a mixture containing six grains of iodide of potassium, 10 grains of bromide of potassium, and five grains of antipyrin every four hours and milk-and soda and brandy every hour Next morning the sickness and headache had abated and the bowels acted after an injection. The patient now complained of great stiffness and soreness in the muscles of the neck and the head was held stiffly but there was no retraction. There was also pain in the back but no hyperæsthesia or anæsthesia of the trunk or the limbs She steadily improved and on June 2nd I was able to send her away for a change.

CASE 4.—The same evening I was sent for to see the fifth child a boy aged two and a half years who was said to be very sick and drowsy His father's account was that he had seemed out of sorts for two or three days. The appetite had been bad and he had occasionally complained of headache. When I saw him he lay curled up in bed and rather resented being moved. The pupils were rather dilated and reacted sluggishly to light. There was no photophobia or head retraction The pulse was 110 and irregular and the temperature was 99 2° F The bowels had not acted for two days in spite of a dose of castor oil, but the tongue was not coated. They acted a little later after a glycerine injection. Next morning vomiting had ceased, but the patient was more drowsy he was however conscious when aroused I ordered an ice bag to be applied to the head and prescribed the same drugs as had been prescribed for the patient in Case 1 In the evening Mr A H. Buck of Brighton kindly came over and saw the patient He recommended a Scott's dressing to be applied to the shaved scalp and milk with a few drops of brandy to be taken every half hour Next day the pulse had improved but the cerebral symptoms progressed rapidly Three days later the patient had convulsions affecting the right arm and leg and convergent squint and he died in the evening Up to the last day he had taken food well and there had been very little wasting The temperature after the first day had remained subnormal. There had been slight retraction of the head during the last two days but no opisthotonos Tache cérébrale had been well marked. Mr Buck examined the eyes with great difficulty owing to the restlessness of the child and thought that the discs were slightly swollen.

CASES 5 and 6.—On June 6th the aunt and on the 12th the father were attacked with symptoms similar to those of the mother—viz. violent headache, sickness stiffness of the neck and constipation. Each recovered in about four days

The other children of the family remain well at present. On Mr Buck's advice they were all sent away on the day following his visit and the family have now moved into another house. Neighbours naturally were anxious to know if the disease was infectious and it was with no confidence that I gave it as my opinion that it was not infectious from person to person but that the fault lay with the house or the soil.

I may add that the house stands on high ground one mile from Crowborough, on the edge of an extensive common The soil is a sandy loam. There are only two other houses within a quarter of a mile of it and these are about 50 yards apart The house contains two sitting rooms and three bed rooms of fair size. Part of the floor of one sitting room was constantly damp until a drain was sunk along the outer wall about two months ago The father told me that when sinking this drain he found that the soil had a very bad smell. The brick floors of the lower rooms are laid directly on the surface of the common without any air course, and the soil is full of decaying vegetable matter I regret that I was unable to obtain a post mortem examination on either of the children.

Uckfield

A CASE OF FRACTURE OF THE SPINE, LAMINECTOMY, RECOVERY

BY R. T BOWDEN M D DURH
SURGEON TO THE RAMSGATE GENERAL HOSPITAL; CONSULTING SURGEON TO THE RAMSGATE AND ST LAWRENCE ROYAL DISPENSARY ETC.

ON June 3rd, 1901 I was called to see a man aged 52 years, who had been knocked down by a runaway horse and water cart. He was standing with his back to the cart and the shaft caught him in the lower dorsal spine and threw him forwards. When I saw him half an hour after the accident he was quite conscious and was complaining of severe pain in the dorsal spine. The power of movement in the lower extremities was limited to an almost imperceptible movement of each great toe. Sensation was unimpaired. The reflexes were absent. It was stated that immediately after the accident he was able to move the legs fairly well. On examination a distinct irregularity could be made out in the spinous processes of the eighth, ninth, and tenth dorsal vertebræ, and on a later occasion, when making another examination, distinct crepitus was detected. In addition to this injury two fingers of the right hand were hopelessly crushed and there was a severe contusion of the right knee together with various other injuries of a slighter nature. The fingers were amputated at once and the patient was placed on a water-bed. A few hours after the accident there was extreme distension of the abdomen from inability to pass flatus per rectum. This caused great distress, but was relieved to some extent by passing a tube into the rectum and by giving large doses of castor oil and turpentine enemata. There was complete retention of urine. The catheter was used regularly and a few hypodermic injections of morphia were given.

On June 8th the patient was seen by Mr. Watson Cheyne who performed laminectomy. The laminæ of the eighth, ninth, and tenth dorsal vertebræ were divided and the intervening bone was removed exposing some three inches of the spinal cord. The pieces of bone removed were fractured in various places and one fragment could be distinctly seen pressing on the cord. Several clots of blood were also removed. On introducing the handle of the scalpel by the side of the cord a fracture of the body of the ninth dorsal vertebra could be detected, the upper fragment being displaced slightly forwards. With a gouge the sharp edge of the lower fragments was smoothed down. The dura mater was not opened. The external wound was sutured and an abundant antiseptic dressing was applied.

The patient did not suffer in any way from the immediate effects of the operation, there was no rise of temperature, and no increased discomfort of any kind was felt. For 10 days the wound was left undisturbed and the patient was then turned gently on his side and the stitches were taken out. The whole wound appeared to have healed by first intention. During the next few weeks the scar was inspected from time to time and all appeared to be going well until July 15th, when there was a sudden rise of temperature with tenderness along the scar and a few days later a small abscess burst leaving a sinus which did not finally heal until three months later.

About three weeks after the laminectomy it was noticed that there was a slight increase in the power of movement in the lower extremities. But at this time and for many weeks afterwards the patient's general condition was unsatisfactory. He was wasting very much; there was no power of expulsion in the rectum which had to be emptied frequently by mechanical means; there was complete retention of urine and the water at times became ammoniacal and offensive. The most scrupulous care was exercised in the use of the catheter and for some months the bladder was washed out daily with boric solution. When the urine became offensive a little boric acid given internally appeared to do much good. Massage and electricity were employed regularly for many months.

It was not until some three months after the accident that any real improvement became manifest. The patient commenced then to put on flesh, the bowels began to act occasionally of their own accord, the urine became acid, but there was still complete retention. Increased power of movement was first noticed in the toes and feet and gradually it extended up the limbs. At the end of another three months he was able to stand and could take a few steps about the room with assistance; the bowels were acting much better though there was still complete retention of urine. From this time onward the progress was steady and continuous, but it was fully nine months after the accident before there was the slightest power to pass urine voluntarily.

The patient's condition at the present time (just a year after the accident) is as follows. He can walk a distance of two miles with hardly any fatigue and he is steadily gaining strength; he feels in perfect health, sleeps and eats well, and is fatter than he has been for years past; the bowels act naturally and he can pass urine fairly well but still finds it advisable to use the catheter once or twice daily. The reflexes are not well marked; a slight patellar reflex can be obtained. Throughout the whole illness the patient exhibited an extraordinary amount of pluck; during all his months of suffering he never lost heart; he said from the first that he intended to surprise his doctors, and he has done so.

Ramsgate.

A CASE OF

RHEUMATIC HYPERPYREXIA FOLLOWED BY SYMPTOMS RESEMBLING THOSE OF DISSEMINATED SCLEROSIS.

BY WILLIAM ALLEN, L.S.A.,
AND
JAMES W. RUSSELL, M.A., M.D. CANTAB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE BIRMINGHAM GENERAL HOSPITAL.

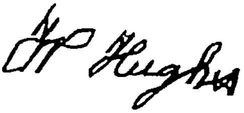
THIS case is of interest less from the extremely high level which the temperature reached than from the nervous lesions by which it was followed.

The patient was a man, aged 30 years, a butcher by occupation, with a good personal and family history. He was attacked with acute rheumatism on Nov. 14th, 1898. The attack ran a mild course and on the morning of Nov. 17th the temperature was normal and the patient's condition was in every way satisfactory. In the course of that day, in consequence of a fright due to the escape of a bull from his yard, he got out of bed and in the evening he was restless and inclined to wander. His temperature was found to be 107° F., but it was quickly reduced by the application of a cold pack. Next morning the temperature had again risen to 107° and though it was again reduced by the further application of cold packs it once more rose to 108°. Early in the afternoon the patient became violently delirious and the mercury reached the end of a thermometer the maximum register of which was 115°. It was certainly above this level. At about 3 P.M. the patient was seen by us together. He was then completely unconscious, the breathing was shallow and irregular, the face was cyanosed, and the whole appearance suggested the immediate approach of death. In a thermometer placed in the axilla, the maximum register of which was 110°, the mercury at once ran up to the extreme limit. The one favourable feature was the state of the pulse, which was hardly so bad as the general condition of the patient led us to expect, and we therefore decided to try once more the vigorous application of cold. As there was no bath in the house a quantity of ice was obtained and packed round the body and limbs and on the head, the chest, and the abdomen, and in the course of three quarters of an hour the temperature slowly came down to 102°, at which point the ice was removed. The temperature subsequently dropped to 98°. During the reduction of the temperature several general convulsions had occurred, and by the end of the hour these were being repeated every few minutes. An hour later the temperature had risen to 99°, and the patient, though still not to be roused, was showing some signs of a return to consciousness. He moved restlessly in bed, made inarticulate sounds, and there was some resistance to passive movement. After this there was a slow return to consciousness, though the ordinary mental condition was not regained for several days. The temperature remained constantly and irregularly raised for the succeeding three weeks, but it only once reached 104°. There were no convulsions after the day of the hyperpyrexia.

On regaining consciousness it was found that the patient had, to a great extent, lost the power of articulate speech and it was with great difficulty that he could make himself understood. There was no aphasia of any description—the difficulty was one of articulation only. Further, when he became convalescent and the weakness left by the fever had somewhat abated it was found that he was quite unable to walk owing to a condition of extreme ataxia of the legs. This slowly improved until the following June, when he was sufficiently improved to be driven into Birmingham, and on June 23rd, 1899, he was for the second time seen by both of us in consultation. The nervous symptoms then only differed from those to be described below as constituting his permanent condition in the greater degree of ataxia of the lower extremities, and we shall here therefore only allude to this feature. The patient was unable to walk or stand without support. With help he walked with short steps, putting each foot forward with great care and much unevenness of movement. On standing with the feet together and the eyes shut there was complete loss of balance. The coördination of the upper extremities was similarly, though to a less extent, affected. The movements of the hands and fingers were unsteady and writing was almost impossible, the pen spluttering and catching on the paper and the attempt being given up finally in despair A fuller report of the nervous symptoms is reserved for the account of the next joint examination, but it should be added that there was even then no evidence of any loss of muscular power nor was there any recognisable rigidity

On May 2nd 1900 we again saw the patient together His condition was as follows —

Motor system.—He was now able to walk by himself and on the whole steadily though every now and then there was a little loss of balance. He walked, however with great care, putting one foot before the other slowly and deliberately saying that he had to be careful lest he should fall The feet were kept rather widely apart and turning was especially difficult. He was quite unable to walk along a line without support. Romberg's sign was but slightly marked but when lifting one foot on to a chair there was marked disorder of movement. The movements of the upper extremities were awkward and clumsy, for instance in attempting to grasp the hand of one of us there was a good deal of coarse, uneven movement. When held out horizontally with the arms close to the body, the hands were steady except for slight wavering on the right side, but if the forefingers were pressed together with the arms well out from the body there was very marked rhythmical coarse tremor There was much unsteadiness in placing the forefinger on the tip of the nose even with the eyes open and there was similar difficulty in bringing the tips of the forefingers together from a distance. The power of writing had considerably improved though the attempt still caused a good deal of tremor which was only controlled by keeping the pen firmly pressed on the paper The following is a specimen of the handwriting —



W Hughes

There was no nystagmus and no tremor of the tongue. The motor power in both upper and lower extremities appeared to be intact, neither was there any paresis of the muscles of the face, the tongue or the eye. There was perhaps a very slight tendency to rigidity of the legs at the beginning of passive movement, but if present it wore off at once and we were not convinced that it really existed. The bladder and rectum were, and had always been, perfectly under control

Speech—Speech was slow monotonous and markedly scanning it would have passed as a most typical example of the scanning speech of disseminated sclerosis The articulation was distinctly though slightly blurred

Sensation.—Sensation was everywhere perfect both to touch and pain. The temperature sense was not tested

Reflexes.—The plantar reflexes were sluggish and flexor in type The knee jerks were moderately increased On testing for ankle clonus a few slight contractions were obtained on each side.

Muscles—The muscles were well nourished and there was no trace of any wasting The electrical reactions were, however somewhat sluggish both to faradism and galvanism Kathodal closing contraction was uniformly greater than was anodal closing contraction

The optic discs were normal and there was no trophic disorder of any sort. General nutrition and health were excellent. The mental faculties were we think quite unimpaired, though the monotonous intonation and blurred articulation gave a *false* air of mental feebleness.

We have recently made a final examination—namely on April 28th, 1902—but have practically nothing to add to the foregoing description. There has been perhaps some gain in control over the finer movements of the limbs, but the gait is still slow and careful The patient is able to do the ordinary work of a butcher's shop and he told us with pride that he had once succeeded in killing a sheep His handwriting is much as before his speech retains the same typical scanning character and in all other respects no change is to be detected

We have searched the literature of hyperpyrexia in rheumatic fever and have only succeeded in finding the report of one similar case. It occurred at the Birmingham General Hospital and was published by Dr Arthur Foxwell in THE LANCET[1] In that case the highest point reached by the temperature was 111° F and it remained raised for 10 days afterwards. The hyperpyrexia occurred on Sept. 28th 1884 and on Oct. 9th it was noticed that there was difficulty in pronouncing consonants and that the intonation was nasal. On Oct. 20th rhythmical tremors were observed the knee jerks were exaggerated more so on the left side and there was right ankle-clonus with a very slight degree of the same condition on the left. Sensation was normal but the leg movements were very feeble and the electrical reactions were sluggish On the 22nd the speech was perceptibly scanning and on the 25th the gait was ataxic and there was slight nystagmus. As in our case considerable improvement subsequently occurred in Dr Foxwell's case, but when the patient was seen a year later there were still some disorder of speech, paresis of the limbs, and tremors the left arm and right leg being most affected Dr Foxwell suggested a diffused inflammation occupying the substance of the medulla and lower half of the pons as a possible explanation of the condition. Some small scattered hæmorrhages would be an alternative solution and the occurrence of convulsions during the hyperpyrexia in our own case would seem to suggest some immediate lesion We have seen one case of rheumatic hyperpyrexia recorded in which such a lesion was present post mortem but have been unable to find the reference.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

OBSERVATIONS ON ERYTHEMA NODOSUM

BY H W SYERS, M A. M.D CANTAB.,
PHYSICIAN TO OUT PATIENTS GREAT NORTHERN CENTRAL HOSPITAL.

THERE is a fixed belief—at all events this is the opinion that would be formed by anyone who takes the trouble to refer to text-books—that the connexion between acute rheumatism and erythema nodosum is a very definite and indeed, close one. Yet an appeal to personal experience—that appeal which is so seldom made—will show that the belief in this link uniting the two maladies is altogether groundless. I have been interested in this question for a long time and have made observations on the nature and affinities of erythema nodosum in a very large number of cases extending over a long series of years. My experience has been that erythema nodosum has nothing whatever to do with rheumatism either acute or chronic. In my cases rheumatism had never preceded or followed the cutaneous lesion, joint pains being entirely absent throughout its course. In every case a most careful examination of the heart was made, but the result was in every instance negative, there being no evidence whatever of valvular or other heart disease. It was equally impossible to associate erythema nodosum with other morbid general conditions and from this point of view the malady should undoubtedly be regarded as *sui generis*

But there is one cutaneous malady to which the symptoms of erythema nodosum are certainly closely allied—urticaria Not long ago I saw a middle aged woman who for four days had been suffering from a rash giving rise to much irritation. The characteristic appearances of erythema nodosum were slightly marked over the shaft of the tibia but on the extensor surfaces of both forearms the rash was very well developed and quite unmistakeable At the same time examination of the neck showed the presence of urticarial wheals situated just where the collar presses If the investigation had been limited to that of the rash on the neck there can be no doubt as to the diagnosis which would have been made that diagnosis would certainly have been urticaria. These patches were anæmic in the centre and were according to the patient's statement extremely fugitive. It is worthy of note, too in this connexion that the skin generally was extremely irritable and that dermographism was well marked. In this case at all events, there can be no doubt that the clinical features of erythema nodosum and of urticaria were combined in one and the same patient But such cases are not so very rare. I have met with them several times The deduction to be drawn from these observations is clearly that the alliances of erythema nodosum are with urticaria and that the malady has nothing to do with rheumatism, acute or chronic

---

[1] THE LANCET, May 29th 1886 p. 1012—"A Case of Rheumatic Hyperpyrexia with Nervous Sequelæ simulating Multiple Sclerosis

As regards the distribution of the lesions in erythema nodosum it is generally considered that the rash is more or less confined to the lower extremities, its seat of election being the front of the tibia, yet in my experience it is by no means unusual to meet with the characteristic appearances on the flexor and extensor surfaces of the arms and forearms as well as the legs and thighs In a few instances I have found the lower extremities to be practically free from the rash which was almost entirely confined to the arms and forearms

It is scarcely necessary to say that the treatment of this malady by salicylates or by anti-rheumatic measures generally is a perfectly futile proceeding The relations of the affection are certainly not with acute rheumatism, hence it is not surprising that therapeutic measures adapted to the management of that malady are altogether fruitless in this disease. Most important of all details of treatment is rest in the recumbent position and the use of lead and opium lotion may be agreeable and soothing to the patient But when severe pain is present warmth seems to be the most efficient method of relieving it. Internally quinine may be administered, but it is more than doubtful if any drugs control the course of the malady

In view of the close relationship existing between erythema nodosum and urticaria it is scarcely necessary to insist upon the importance of attention being devoted to the diet, the condition of the stomach, and the state of the bowels

Wimpole-street, W

A CASE OF CHRONIC PULMONARY TUBERCULOSIS TERMINATING IN ACUTE SURGICAL EMPHYSEMA.

BY J F HODGSON, M B, CH.B VICT,

RESIDENT MEDICAL OFFICER HALIFAX UNION POOR LAW HOSPITAL.

IT is probably a rare occurrence for a case of chronic pulmonary tuberculosis to terminate in acute surgical emphysema Such a state of things was found in the case of a patient in the Halifax Union Poor law Hospital.

The patient was a man, aged 41 years. He had been phthisical for 25 years and presented all the signs of chronic pulmonary tuberculosis When I saw him on the day of his death he was suffering excruciating pain in the region of his left shoulder A slight emphysematous puffiness on the left side of his neck was all that could be made out then. The emphysema was very acute, two and a half hours only elapsing between the appearance of the first symptom and death The patient, naturally a very thin man, soon became enormously distended. The emphysema was general, the skin all over the body being very tightly stretched.

At the post-mortem examination on opening the thorax the right lung was found to be fixed to the chest wall in places by old adhesions The lung itself showed evidence of old standing phthisical lesions. The left pleural cavity was entirely obliterated, it being quite impossible to separate the lung from the chest wall. On attempting to do this there was disclosed, situated at the posterior portion of the apex of the left lung, a cavity of the size of a pigeon's egg Projecting into this cavity was a sharp spicule of bone A portion of the thick cap of pleura covering the apex of the left lung was necrosed opposite to the third left rib The inflammatory process had spread to the bone and so weakened it that it had snapped about two inches from its vertebral end. Very little force must have sufficed for this, as the patient was kept in bed and had very little cough

I am indebted to Mr J F Woodyatt, the principal medical officer for permission to publish the case.

Halifax

A SERIES OF CASES OF JAUNDICE IN THE FŒTUS

BY G FRANCIS SMITH, M R.C S ENG, L R C P LOND

IT is no uncommon thing to meet with a mild attack of jaundice in the newly born infant, but I believe that the same condition in the fœtus is rare, and still more so when the resulting poisoning causes death, as described in the following cases, all children of the same mother

Four years ago a patient under my care, then aged 29 years, was delivered of a male child who was free from jaundice and who is now living At the age of two years he had a very severe attack which at the time I attributed to obstructive catarrh of the bile-ducts Three years ago the same woman had another boy born The child was full time but stillborn. He was intensely yellow, as were the liquor amnii, the membranes, and the placenta, all of them being deeply stained with bile. Death had presumably occurred one week before birth Two years ago another boy was born and the same condition of the liquor amnii and membranes obtained The child, who lived three days, was green at birth and became more so afterwards Symptoms of bile-poisoning supervened, terminating in coma. One year ago a girl was born Here again the same condition prevailed, only that the child lived five days On June 26th, 1902, another boy was born The liquor amnii was less dark and the child was less stained than on the previous occasions, but here, again, life seemed to flicker a few hours after birth The child would not take the breast, cried pitifully and moaned, gradually became comatose, and died on the third day

In none of these cases was there obstruction to the flow of bile into the intestines, for the first and subsequent motions were deeply bile stained The mother had one attack of jaundice some three and a half years ago whilst pregnant with the child that was stillborn She is otherwise healthy though fragile-looking The father is the picture of health and strength and the family history is good on both sides I am utterly at a loss to account for these strange cases and I cannot even suggest a probable cause of the jaundice, or rather the excessive secretion of bile, which in each case was present before birth and was the direct cause of death

WESTMINSTER HOSPITAL

A CASE OF SPLENIC LEUKÆMIA TERMINATING IN TUBERCULOSIS.

(Under the care of Dr W MURRELL.)

THE association of tuberculosis with splenic leukæmia is so rare that it is very desirable that every case in which these two conditions coexist should be published. The completeness with which the details of the following case are recorded greatly enhances its value

A woman, aged 21 years, was admitted into Westminster Hospital on July 9th, 1901, complaining of general weakness and debility She stated that she was perfectly well until the previous September, when after an attack of influenza she noticed a swelling in the abdomen on the left side. Three months later she had rheumatic fever with which she was laid up for eight weeks Failing to recover her strength and experiencing some discomfort from the swelling she went to the Charing Cross Hospital, where she was treated with arsenic, iron, and galvanism with benefit She stated that both her father and mother were living and well. She had four sisters, all of whom suffered from anæmia, and two brothers who were in good health Her mother's brother died from phthisis at the age of 35 years and two of her maternal aunt's children died from the same disease.

On admission, and for some days after, her temperature varied from 100° to 101° F She was pale but not markedly so, and there was dyspnœa on exertion There was a considerable amount of pigmentation, especially of the abdomen and in the neighbourhood of the axillæ, nipples, and groins. There were brown pigment spots ranging in size from that of a pin's head to that of a split pea on the arms and there were similar spots scattered over the face. There were no patches of pigment on the mucous membranes. The spleen was felt as a smooth, firm, hard tumour extending anteriorly to the umbilicus and downwards well into the hypogastric region, there was a tender spot at the margin of the ninth and tenth ribs and the notches on the anterior border could be felt without difficulty The circumference of the abdomen at the umbilicus was 31 inches and there was no ascites. There was no enlargement of the cervical axillary or inguinal glands and there was no tenderness of the bones. The red blood corpuscles numbered 4 735,000 per cubic millimetre and the white 44 000 the latter consisting of finely granular oxyphile cells 51 per cent. coarsely granular 4 per cent., hyaline cells 15 per cent. lymphocytes 9 per cent. and myelocytes 26 per cent. These percentages are only approximately correct, as it was found impossible, from the large number of transitional forms observed to differentiate the varieties with any approach to certainty There was no epistaxis, menorrhagia, or other form of hæmorrhage, and there was no retinitis. She had a faint apex systolic murmur The urine was acid of specific gravity 1032, and contained no albumin or sugar It was found that 100 cubic centimetres of urine contained 2 5 grammes of uric acid. The patient was kept in bed and under close observation until May 21st, 1902, when she died. During the last few days of life there were indications of œdema of the lungs with consolidation at the left base. There was very little cough and no expectoration. The progress of the case is best seen by the following analysis of the symptoms and physical signs.

Temperature —The temperature was taken six times in the 24 hours. For the first month it was rarely above 99° although occasionally it rose to 101° at 11 p.m In August and September it ranged from 97° or 98° in the morning to 102° in the evening After this there was a long period of quiescence in which the temperature rarely rose above 99° In January and February it ranged daily from 98° to 101 8° In March and April it was persistently high rarely falling below 101° During the last week of life it varied from 101° to 102 6° the pulse being from 120 to 130 and the respirations from 40 to 44 in the minute.

Blood —The blood was examined from time to time by Dr Lazarus-Barlow Dr Bertram Abrahams, and Mr E. Rock Carling and the following data were obtained —

Date.	Time.	Erythrocytes per cubic millimetre	Leucocytes per cubic millimetre.	Hæmoglobin value per cent.
July 24th 1901	11.30 A.M	4 125,000	71 000	85
August 10th	4 P M	3,127 000	192,000	61
Sept 11th	2 P.M	3,780 000	220 000	45
Oct. 17th	3.15 P.M	4 390 000	150 000	64
20th	2 P.M	4 030,000	20,000	58
„ 27th	3 P.M.	2,850 000	29,500	58
Nov 4th „	3.30 P.M	3,475,000	22,900	60
April 6th, 1902	—	—	167 000	—
May 14th	1 45 P M	2,660 000	16,200	—

The percentage of the different forms of leucocytes varied much from time to time. For example, on Oct. 20th it was as follows small lymphocytes, 10 per cent. large lymphocytes 5 per cent. myelocytes, 20 per cent., polymorphonuclears, 45 per cent. and eosinophiles, 20 per cent. Seven days later the following figures were recorded small lymphocytes, 3 per cent. large 3 per cent. myelocytes (chiefly eosinophilous) 44 per cent. polymorphonuclears, 30 per cent. and eosinophiles, 20 per cent. The sudden fall in the number of leucocytes from 150,000 on Oct. 17th to 20,000 on the 20th was coincident with the appearance of the catamenia on the evening of the 17th and a higher temperature on the 18th and 19th than had been recorded for some days previously In the final count on May 14th when the leucocytes had fallen to 16,200 the percentages were as follows finely granular 45 lymphocytes, 9 myelocytes 7, basophile, 7 and hyaline, 36. A large proportion of those classed as "finely granular" were atypical as to nucleus. Speaking generally of the blood observations made throughout the case it may be said that the great increase was in cells of large size presenting a large badly staining circular or oval nucleus and in the number of very minute granules which stained with eosine. The fall in the number of myelocytes towards the end was very noticeable On Oct. 27th the differential count per cent was 44 on Nov 4th it was 20 and on May 14th it was only seven. The polymorphonuclears on Nov 4th were 25 per cent. and on May 14th they were 45 per cent.

Spleen.—The spleen continued to increase in size until the middle of January when it was two inches to the right of the umbilicus and extended downwards almost to Poupart's ligament In then rapidly diminished in volume until on April 25th, 1902, it was two inches to the left of the umbilicus and proportionately smaller in other directions.

Hæmorrhages —From February onwards the patient suffered from extensive subcutaneous hæmorrhages chiefly on the lower extremities and the right knee was red and painful. In April the extraction of a tooth was followed by a not unusual amount of bleeding The eyes were frequently examined by Mr G Hartridge. In July 1901, the fundi were normal, in December the retinal veins were large and tortuous three times the size of the arteries, and the discs showed a few hæmorrhages in the periphery In March the retinal vessels were extremely tortuous and much enlarged and there was some increase in the amount of hæmorrhage. The ears were examined but there was no deafness and nothing abnormal was found.

Pigmentation.—The pigmentation noticed on admission persisted and increased somewhat whilst the patient was taking arsenic. A dark purple line was observed at the base of the nails. In this connexion it may be mentioned that the patellar reflex was absent.

The treatment adopted was as follows. From July 14th to 27th and from August 28th to Sept 21st the patient had liquor arsenicalis in doses of from three to 15 minims three times a day From Oct 2nd to Nov 9th she had liquor hydrargyri perchloridi in from three- to five-minim doses every four hours. She was then placed on sulphate of quinine in five-grain doses three times a day for some weeks, after which she had sodium meta vanadate in daily doses of two milligrammes. Probably none of these drugs exerted any real effect on the progress of the disease, but the administration of the small doses of perchloride of mercury was concurrent with the decrease in the number of leucocytes.

Necropsy —At the post-mortem examination (which was made by Mr Carling) the pleural sacs were each found to contain about half a pint of clear serous exudate the pleural membrane was smooth and not ecchymosed. In both lobes of the left lung and in the upper lobe of the right there were patches of consolidation presenting the appearance of grey hepatisation at the apex of the left was an area of caseation with breaking-down. The larynx, trachea, and bronchi were normal but in the latter there was muco-purulent secretion. The thyroid was normal. In the situation of the thymus there was a mass of tissue. The infra tracheal glands were much enlarged and pigmented and in one there was a patch of breaking down caseation. The spleen (which weighed 3 pounds 12 ounces) was firm, resisted cutting and was brownish red on section. The capsule was not disproportionately thick. Scattered throughout the organ and here and there on the surface were white masses apparently of miliary tubercle. The liver weighed 5 pounds, it was pale and firm and showed both on the surface and on section miliary tubercles The adrenals were normal. The marrow of the ribs was pale in colour and small in quantity That of the lower end of the femur was firm, in part grey and in part red interlaced with white trabeculæ. On microscopical examination it was found that in the lungs there were abundant evidences of tubercle. The indications in the liver were less decisive but there seemed to be early tubercle. There was no doubt that the patient died from tuberculosis. (The specimens and sections have been kept.)

Remarks by Dr MURRELL.—Cases of splenic myelogenous leukæmia with pulmonary tuberculosis are extremely rare There are, I think, only two previous cases on record It is stated on the authority of Elsner and Groat that clinicians and pathologists of such wide experience as Stengel Osler Cabot, Packlen and Janeway have never seen a case. In 1897 Lichtheim[1] published a case but it was of the lymphatic and not of the splenic myelogenous type. It is interesting however as a table is appended showing the marked reduction in the number of leucocytes as the tuberculosis progressed. The first count in November 1896 gave events, there can be no doubt that the clinical features of erythema nodosum and of urticaria were combined in one and the same patient. But such cases are not so very rare. I have met with them several times The deduction to be drawn from these observations is clearly that the alliances of erythema nodosum are with urticaria and that the malady has nothing to do with rheumatism, acute or chronic.

---

[1] *Deutsche Medicinische Wochenschrift* Sept. 30th, 1897 p 193.

As regards the distribution of the lesions in erythema nodosum it is generally considered that the rash is more or less confined to the lower extremities, its seat of election being the front of the tibia, yet in my experience it is by no means unusual to meet with the characteristic appearances on the flexor and extensor surfaces of the arms and forearms as well as the legs and thighs In a few instances I have found the lower extremities to be practically free from the rash which was almost entirely confined to the arms and forearms

It is scarcely necessary to say that the treatment of this malady by salicylates or by anti rheumatic measures generally is a perfectly futile proceeding The relations of the affection are certainly not with acute rheumatism, hence it is not surprising that therapeutic measures adapted to the management of that malady are altogether fruitless in this disease. Most important of all details of treatment is rest in the recumbent position and the use of lead and opium lotion may be agreeable and soothing to the patient. But when severe pain is present warmth seems to be the most efficient method of relieving it. Internally quinine may be administered, but it is more than doubtful if any drugs control the course of the malady

In view of the close relationship existing between erythema nodosum and urticaria it is scarcely necessary to insist upon the importance of attention being devoted to the diet, the condition of the stomach and the state of the bowels

A CASE OF CHRONIC PULMONARY TUBERCULOSIS TERMINATING IN ACUTE SURGICAL EMPHYSEMA.

BY J F HODGSON, M B, CH.B VICT,
RESIDENT MEDICAL OFFICER HALIFAX UNION POOR LAW HOSPITAL.

IT is probably a rare occurrence for a case of chronic pulmonary tuberculosis to terminate in acute surgical emphysema. Such a state of things was found in the case of a patient in the Halifax Union Poor law Hospital.

The patient was a man, aged 41 years. He had been phthisical for 25 years and presented all the signs of chronic pulmonary tuberculosis When I saw him on the day of his death he was suffering excruciating pain in the region of his left shoulder A slight emphysematous puffiness on the left side of his neck was all that could be made out then. The emphysema was very acute, two and a half hours only elapsing between the appearance of the first symptom and death. The patient, naturally a very thin man, soon became enormously distended. The emphysema was general, the skin all over the body being very tightly stretched.

At the post-mortem examination on opening the thorax the right lung was found to be fixed to the chest wall in places by old adhesions The lung itself showed evidence of old standing phthisical lesions. The left pleural cavity was entirely obliterated, it being quite impossible to separate the lung from the chest wall. On attempting to do this there was disclosed, situated at the posterior portion of the apex of the left lung, a cavity of the size of a pigeon's egg Projecting into this cavity was a sharp spicule of bone. A portion of the thick cap of pleura covering the apex of the left lung was necrosed opposite to the third left rib The inflammatory process had spread to the bone and so weakened it that it had snapped about two inches from its vertebral end. Very little force must have sufficed for this, as the patient was kept in bed and had very little cough.

I am indebted to Mr J F Woodyatt, the principal medical officer for permission to publish the case.

Halifax.

A SERIES OF CASES OF JAUNDICE IN THE FŒTUS

BY G FRANCIS SMITH, M.R.C S ENG, L.R.C P LOND

IT is no uncommon thing to meet with a mild attack of jaundice in the newly born infant, but I believe that the same condition in the fœtus is rare, and still more so when the resulting poisoning causes death, as described in the following cases, all children of the same mother

Four years ago a patient under my care, then aged 29 years, was delivered of a male child who was free from jaundice and who is now living At the age of two years he had a very severe attack which at the time I attributed to obstructive catarrh of the bile-ducts Three years ago the same woman had another boy born The child was full time but stillborn. He was intensely yellow, as were the liquor amnii, the membranes, and the placenta, all of them being deeply stained with bile. Death had presumably occurred one week before birth. Two years ago another boy was born and the same condition of the liquor amnii and membranes obtained The child, who lived three days, was green at birth and became more so afterwards Symptoms of bile-poisoning supervened, terminating in coma. One year ago a girl was born Here again the same condition prevailed, only that the child lived five days On June 26th, 1902, another boy was born The liquor amnii was less dark and the child was less stained than on the previous occasions, but here, again, life seemed to flicker a few hours after birth. The child would not take the breast, cried pitifully and moaned, gradually became comatose, and died on the third day

In none of these cases was there obstruction to the flow of bile into the intestines, for the first and subsequent motions were deeply bile-stained. The mother had one attack of jaundice some three and a half years ago whilst pregnant with the child that was stillborn. She is otherwise healthy though fragile-looking The father is the picture of health and strength and the family history is good on both sides I am utterly at a loss to account for these strange cases and I cannot even suggest a probable cause of the jaundice, or rather the excessive secretion of bile which in each case was present before birth and was the direct cause of death

WESTMINSTER HOSPITAL

A CASE OF SPLENIC LEUKÆMIA TERMINATING IN TUBERCULOSIS.

(Under the care of Dr W MURRELL.)

THE association of tuberculosis with splenic leukæmia is so rare that it is very desirable that every case in which these two conditions coexist should be published. The completeness with which the details of the following case are recorded greatly enhances its value.

A woman, aged 21 years was admitted into Westminster Hospital on July 9th, 1901, complaining of general weakness and debility She stated that she was perfectly well until the previous September, when after an attack of influenza she noticed a swelling in the abdomen on the left side. Three months later she had rheumatic fever with which she was laid up for eight weeks Failing to recover her strength and experiencing some discomfort from the swelling she went to the Charing Cross Hospital, where she was treated with arsenic, iron, and galvanism with benefit. She stated that both her father and mother were living and well. She had four sisters, all of whom suffered from anæmia, and two brothers who were in good health Her mother's brother died from phthisis at the age of 35 years and two of her maternal aunt's children died from the same disease.

On admission, and for some days after, her temperature varied from 100° to 101° F She was pale but not markedly so, and there was dyspnœa on exertion There was a considerable amount of pigmentation especially of the abdomen and in the neighbourhood of the axillæ, nipples, and groins. There were brown pigment spots ranging in size from that of a pin s head to that of a split pea on the arms and there were similar spots scattered over the face. There were no patches of pigment on the mucous membranes. The spleen was felt as a smooth, firm, hard tumour extending anteriorly to the umbilicus and downwards well into the hypogastric region there was a tender spot at the margin of the ninth and tenth ribs and the notches on the anterior border could be felt without difficulty The circumference of the abdomen at the umbilicus was 31 inches and there was no ascites. There was no enlargement of the cervical, axillary or inguinal glands and there was no tenderness of the bones. The red blood corpuscles numbered 4 735,000 per cubic millimetre and the white 44 000 the latter consisting of finely granular oxyphile cells 51 per cent. coarsely granular 4 per cent. hyaline cells 15 per cent. lymphocytes 9 per cent. and myelocytes 28 per cent. These percentages are only approximately correct, as it was found impossible, from the large number of transitional forms observed to differentiate the varieties with any approach to certainty There was no epistaxis, menorrhagia, or other form of hæmorrhage, and there was no retinitis. She had a faint apex systolic murmur The urine was acid of specific gravity 1032, and contained no albumin or sugar It was found that 100 cubic centimetres of urine contained 2 5 grammes of uric acid. The patient was kept in bed and under close observation until May 21st, 1902, when she died. During the last few days of life there were indications of œdema of the lungs with consolidation at the left base. There was very little cough and no expectoration. The progress of the case is best seen by the following analysis of the symptoms and physical signs.

Temperature —The temperature was taken six times in the 24 hours. For the first month it was rarely above 99° although occasionally it rose to 101° at 11 p m. In August and September it ranged from 97° or 98° in the morning to 102° in the evening After this there was a long period of quiescence in which the temperature rarely rose above 99° In January and February it ranged daily from 98° to 101 8° In March and April it was persistently high, rarely falling below 101° During the last week of life it varied from 101° to 102 6° the pulse being from 120 to 130 and the respirations from 40 to 44 in the minute.

Blood —The blood was examined from time to time by Dr Lazarus-Barlow Dr Bertram Abrahams, and Mr E. Rock Carling and the following data were obtained —

Date.	Time.	Erythrocytes per cubic millimetre	Leucocytes per cubic millimetre.	Hæmoglobin value per cent.
July 24th, 1901 ...	11.30 A.M	4 125,000	71 000	85
August 10th ..	4 P.M	3 127 000	182,000	61
Sept 11th " ..	2 P.M	3,780 000	220 000	45
Oct 17th " ...	3 15 P M	4,390,000	150 000	64
20th ...	2 P.M.	4 030 000	20 000	66
27th ..	3 P.M.	2,860,000	29 500	65
Nov 4th ...	3.30 P.M	3,475,000	22,900	60
April 5th 1902 ..	—	—	167 000	—
May 14th ..	1.45 P M.	2,660,000	16,200	—

The percentage of the different forms of leucocytes varied much from time to time. For example on Oct. 20th it was as follows small lymphocytes, 10 per cent. large lymphocytes 5 per cent. myelocytes 20 per cent. polymorphonuclears, 45 per cent. , and eosinophiles, 20 per cent. Seven days later the following figures were recorded small lymphocytes 3 per cent. large, 3 per cent. , myelocytes (chiefly eosinophilous) 44 per cent. polymorphonuclears, 30 per cent. and eosinophiles, 20 per cent. The sudden fall in the number of leucocytes from 150,000 on Oct. 17th to 20 000 on the 20th was coincident with the appearance of the catamenia on the evening of the 17th and a higher temperature on the 18th and 19th than had been recorded for some days previously In the final count on May 14th when the leucocytes had fallen to 16 200 the percentages were as follows finely granular 45 lymphocytes 9 myelocytes 7 basophile, 7 and hyaline, 38. A large proportion of those classed as finely granular' were atypical as to nucleus. Speaking generally of the blood observations made throughout the case it may be said that the great increase was in cells of large size, presenting a large badly staining circular or oval nucleus and in the number of very minute granules which stained with eosine. The fall in the number of myelocytes towards the end was very noticeable On Oct. 27th the differential count per cent. was 44 on Nov 4th it was 20 and on May 14th it was only seven. The polymorphonuclears on Nov 4th were 25 per cent. and on May 14th they were 45 per cent.

Spleen —The spleen continued to increase in size until the middle of January when it was two inches to the right of the umbilicus and extended downwards almost to Poupart s ligament In then rapidly diminished in volume until on April 25th 1902, it was two inches to the left of the umbilicus and proportionately smaller in other directions.

Hæmorrhages —From February onwards the patient suffered from extensive subcutaneous hæmorrhages chiefly on the lower extremities, and the right knee was red and painful. In April the extraction of a tooth was followed by a not unusual amount of bleeding The eyes were frequently examined by Mr G Hartridge. In July 1901, the fundi were normal in December the retinal veins were large and tortuous, three times the size of the arteries and the discs showed a few hæmorrhages in the periphery In March the retinal vessels were extremely tortuous and much enlarged, and there was some increase in the amount of hæmorrhage. The ears were examined but there was no deafness and nothing abnormal was found

Pigmentation.—The pigmentation noticed on admission persisted and increased somewhat whilst the patient was taking arsenic. A dark purple line was observed at the base of the nails. In this connexion it may be mentioned that the patellar reflex was absent.

The treatment adopted was as follows From July 14th to 27th and from August 28th to Sept 21st the patient had liquor arsenicalis in doses of from three to 15 minims three times a day From Oct. 2nd to Nov 9th she had liquor hydrargyri perchloridi in from three- to five minim doses every four hours. She was then placed on sulphate of quinine in five-grain doses three times a day for some weeks, after which she had sodium meta vanadate in daily doses of two milligrammes. Probably none of these drugs exerted any real effect on the progress of the disease, but the administration of the small doses of perchloride of mercury was concurrent with the decrease in the number of leucocytes

Necropsy —At the post-mortem examination (which was made by Mr Carling) the pleural sacs were each found to contain about half a pint of clear serous exudate the pleural membrane was smooth and not ecchymosed. In both lobes of the left lung and in the upper lobe of the right there were patches of consolidation presenting the appearance of grey hepatisation , at the apex of the left was an area of caseation with breaking-down. The larynx, trachea, and bronchi were normal but in the latter there was muco-purulent secretion. The thyroid was normal In the situation of the thymus there was a mass of tissue. The infra tracheal glands were much enlarged and pigmented and in one there was a patch of breaking down caseation. The spleen (which weighed 3 pounds 12 ounces) was firm, resisted cutting and was brownish red on section. The capsule was not disproportionately thick. Scattered throughout the organ and here and there on the surface were white masses apparently of miliary tubercle. The liver weighed 5 pounds it was pale and firm and showed both on the surface and on section miliary tubercles. The adrenals were normal. The marrow of the ribs was pale in colour and small in quantity That of the lower end of the femur was firm in part grey and in part red, interlaced with white trabeculæ. On microscopical examination it was found that in the lungs there were abundant evidences of tubercle. The indications in the liver were less decisive but there seemed to be early tubercle There was no doubt that the patient died from tuberculosis. (The specimens and sections have been kept.)

Remarks by DR MURRELL —Cases of splenic myelogenous leukæmia with pulmonary tuberculosis are extremely rare There are I think, only two previous cases on record. It is stated on the authority of Eisner and Groat that clinicians and pathologists of such wide experience as Stengel Osler Cabot, Pudden, and Janeway have never seen a case. In 1897 Lichtheim[1] published a case but it was of the lymphatic and not of the splenic-myelogenous type. It is interesting however, as a table is appended showing the marked reduction in the number of leucocytes as the tuberculosis progressed. The first count in November 1896, gave

---

[1] Deutsche Medicinische Wochenschrift Sept [illegible]0th 1897 p 193.

2,000,000 red blood corpuscles and 250,000 white per cubic millimetre, whilst in the following February the red corpuscles were 3,300,000 and the white were 8900 Under the influence of the intercurrent disease the proportion of leucocytes to erythrocytes diminished from 1 in 8 to 1 in 370 In 1889 Quincke[2] at the Association of German Scientists and Physicians in Heidelberg reported a case of mixed splenic-myelogenous and lymphatic leukæmia in which miliary tuberculosis supervened There was a marked reduction in the characteristic leucocytes but no differential counts are given At the same meeting Stintzing[3] reported a case of lymphatic leukæmia in which there was chronic tuberculosis. At the expiration of six months there were the physical signs of cavities at the apices of the lungs and the sputum contained tubercle bacilli The blood at first showed moderate leukæmia (1 in 100) with a normal red count, but as the tuberculosis progressed the glands became smaller and the proportion of leucocytes was reduced to 1 in 150 Baldwin[4] in the same year reported a case of lymphatic leukæmia with tuberculosis and gave a series of differential blood counts At the first examination in October, 1897 the erythrocytes were 3,010,000 and the leucocytes were 695,000, whilst in December, 1897 on the day immediately preceding death, there were 2,435,500 red and 959,500 white per cubic millimetre, the proportion of white to red having risen from 1 in 4½ to 1 in 2½ The first case of splenic myelogenous leukæmia with pulmonary tuberculosis was published in 1901 by Henry L. Elsner and William A. Groat[5] of the Syracuse University The patient, a man, aged 40 years, after being under observation for some weeks, developed phthisis with well marked physical signs in the lungs and tubercle bacilli in the expectoration His blood was examined on six different occasions and showed a gradual diminution in the white cells from 320,000 to 121,500 per cubic millimetre and a decrease of myelocytes from 31 per cent. to 17 5 per cent The second case was published by Arnold Sturmdorf[6] of New York. The patient was a woman, aged 35 years, who developed pulmonary laryngeal and faucial tuberculosis Blood counts were made during a period of four weeks and showed that each rise of temperature was accompanied by a corresponding increase in the number of polymorphonuclears and a proportionate decrease in myelocytes

Although phthisis is rare in splenic myelogenous leukæmia it is not uncommon to meet with an ulcerative process and new formations disseminated throughout the lungs giving rise to small scattered cavities. Lymphoid cells infiltrate the wall of the bronchus and extend into the adjacent pulmonary tissue Nodules are formed which may coalesce into larger masses, although they rarely undergo caseation. The infiltration may be present in three situations—around the branches of the pulmonary vessels, around the bronchi and alveoli, and beneath the pleura. In the fibrinous areas so formed large collections of bacteria are often found. The diagnosis of tubercle as a superadded affection in leukæmia presents much difficulty The temperature affords no indication, for it is commonly elevated from the original disease The patient may have very little cough and no expectoration, and the physical signs may be ascribed to œdema of the lungs or a patch of pneumonic consolidation. A reduction in the percentage of myelocytes with an increase in the polymorphonuclears should excite suspicion

Of other intercurrent affections in leukæmia erysipelas is the commonest. In a case reported by Richter[7] the patient suffered from an attack of acute rheumatic arthritis, whilst Müller's case[8] was complicated with septicæmia In the rheumatic patient the condition of the blood remained unaltered but in the septicæmic case the white cells rose from 180,000 to 400,000 per cubic millimetre, with a marked increase in the percentage of polymorphonuclears There was a genuine leucocytosis added to a leukæmia In intercurrent affections such as pneumonia and pleurisy, which in the normal blood produce a leucocytosis, the total number of leucocytes is decreased and may fall below the normal as death draws near

A point which attracted attention in this case was the extensive pigmentation Was it due to the arsenic which the patient took before she came under my care or was it to be regarded as an indication that the adrenals were involved? Dr Robert Muir informs me that in his experience involvement of these organs is rare Professor Ralph Stockman, who saw the case with me, was of opinion that the pigmentation was due to arsenic and at the necropsy the adrenals were found to be normal These organs have been found diseased in a few cases of leukæmia. In one they were the seat of caseous change and in another in which they were large and mottled there was some bronzing of the skin In connexion with the action of arsenic in causing pigmentation of the skin it will be remembered that even small doses in frogs induced desquamation, the cuticle being stripped off readily from every part of the body This desquamation is observed[9] in as short a period as five and a half hours after the administration of a proportional dose of $\frac{1}{1000}$ The histological explanation of the change has been investigated by Emily A. Nunn[10] who has shown that (1) the whole epiderm becomes loosed from the subjacent derm, (2) the cells of the Malpighian layer become incoherent so that the whole layer collapses, its well known architectural features becoming obscured, and (3) the intermediate layer separates from the Malpighian layer below and from the corneous layer above

Arsenic is reputed to be of value in the treatment of leukæmia, but in this case it was less efficacious than small and frequently repeated doses of perchloride of mercury On theoretical grounds it would hardly be expected that arsenic would do much good in splenic leukæmia, for, as R Stockman and E D W Greig[11] have pointed out, it acts as a hæmatinic by stimulating the bone marrow Although it may increase the number of blood corpuscles it does not affect the cause of the disease, and its administration is a purely symptomatic mode of treatment. With regard to vanadium its efficacy is equally doubtful. It is allied in action to phosphorus and arsenic, although there are many points of difference G F Dowdeswell[12] many years ago showed that in animals it produced fatty degeneration of the liver Recently, Lyonnet, Martz, and Martin[13] in a joint paper, "De l'Emploi Thérapeutique des Sels de Vanadium (Métavanadate de Soude)," have advocated its use in a number of diseases, including anæmia, but apparently not of the pernicious type They say that it markedly improves the appetite, imparts a sense of well being and increases the body weight. They give the sodium meta-vanadate by mouth in daily doses of from one to five milligrammes The most exhaustive paper on the physiological action of the drug is by John Priestley[14] of Manchester, the result of a research made under the direction of Professor Arthur Gamgee, F R S In this contribution it is shown that vanadium exerts no direct action on the blood Many French writers on vanadium speak of "les recherches de Platt," evidently being misled by the fact that Priestley was the Platt physiological scholar at Owens College

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON

Puerperal Eclampsia —Retro-peritoneal Lipoma —Ovarian Tumour in the Pelvis

A MEETING of this society was held on July 2nd, Dr PETER HORROCKS, the President, being in the chair

Dr R H. BELL read a short communication on a case of Puerperal Eclampsia with Necropsy and Remarks The clinical phenomena were those usually associated with cases of eclampsia, viz, headache, vomiting, œdema, albuminuria, and, finally, fits and coma. It was noted, however, that the urine was little, if at all, diminished in amount, and that albumin, though always present, was never in larger proportions than one sixth The presence of jaundice in the later stages of the illness was also mentioned, and reference was made to other cases in which this symptom was present.

[14] Transactions of the Royal Society of London, 1876 vol clxvi, p 495 THE LANCET Jan 15th 1876 p 104

A short account followed of the necropsy and microscopical appearances of the liver and kidneys, both of which but especially the former, showed marked degenerative changes such as have been described by Pelliet and others as associated with cases of eclampsia Their close resemblance to those seen in the early stages of acute yellow atrophy was dwelt upon, but the fact was mentioned that during life no diminution of the size of the liver was made out, and that post mortem the organ weighed 55 ounces. Dr Bell suggested that the case was interesting as showing the close affinity of eclampsia to acute yellow atrophy occurring in a pregnant woman, the post mortem appearances being those associated with an acute toxæmia. Some experiments with regard to the toxicity of the blood conducted by Mr O G Seligmann were then recorded. The method employed was the subcutaneous injection of serum into guinea pigs. Control experiments were made with the blood from cases of chronic uræmia in the stage of coma, and it was shown that in these cases the serum had by no means the same high degree of toxicity as existed in the ca e of eclampsia.—Dr C J CULLINGWORTH thought that there was much that was still to be elucidated both about the pathology of puerperal eclampsia and that of acute yellow atrophy of the liver and it was quite possible that some day both might be found to be capable of being classed under one general heading The difficulties of such a case as this would then be cleared up and indeed this case might prove valuable as a sort of connecting link, all the more valuable from its having been recorded without any attempt to fit the facts on to some favourite theory There was just one point on which he should like to ask Dr Bell a question. The hæmorrhages found in the liver were extensive and remarkable He was not sure that their extent had been actually measured and recorded in figures, but from his recollection he should say that the larger one had a sectional area of at lea t three *inches by two and a half inches.* He feared that he was not a sufficiently expert pathologist to be able to say whether such a condition was ever met with in puerperal eclampsia with kidney lesions only —Dr T W EDEN said that he thought the case which had been so admirably reported by Dr Bell was a very important one. It served to support the view now gaining much favour abroad that it was possible to divide cases of eclampsia into two principal groups hepatic and renal. The morbid anatomy of eclampsia had not perhaps received as much attention of late as had been paid to experimental work in connexion with the toxæmic theory of this disorder But the occurrence of well-defined changes in the liver consisting chiefly of hæmorrhages and degeneration of hepatic cells, was now well established and it had of course, been long recognised that marked changes might also be found in the kidneys Dr Bell s case appeared to belong to the hepatic class, and the relation of this class to cases of acute yellow atrophy was one of the most interesting problems connected with the subject. Dr Bell appeared to sympathise with the view that eclampsia was produced by a toxic condition of the blood. That might be so but toxæmia after all was only a symptom like eclampsia, and they were therefore no nearer a satisfactory explanation of the pathology of the condition. The real problem that had to be faced was How did the toxæmia arise? Unfortunately no answer could at present be given to this question When physiological chemists had succeeded in separating from the blood of eclamptic women definite toxic bodies the properties of which could be accurately studied some progress might be made in settling this very difficult question.—Dr AMAND J M ROUTH rather doubted the diagnosis of acute yellow atrophy in this case owing to the absence of atrophy He saw a patient, six months pregnant, who was seized with severe vomiting slight albuminuria, jaundice and passage of blood per rectum. A diagnosis of acute yellow atrophy was made and the uterus was emptied. The following day puerperal eclampsia ensued and she died but no post-mortem examination was allowed.—The PRESIDENT did not think that this was an ordinary case of puerperal eclampsia. On the contrary it was a very unusual one, for on the one hand the urine was never loaded with albumin and on the other albumin was not quite absent. Again there was marked jaundice which was uncommon in puerperal eclampsia. Hence although the pathological changes in the liver and other viscera were of great interest it did not follow that they would be found in ordinary cases. He deprecated the use of the term puerperal toxæmia. for it was founded upon a still unproved theory and gave no picture of the case like the term puerperal eclampsia" did.—Dr G H DRUMMOND ROBINSON referred to a case in which he had made some experiments with the blood serum of a patient who, during her first pregnancy had developed jaundice and albuminuria. Considerable quantities of the blood serum from this case were injected into guinea pigs without producing any effect. This patient had no fits and made a good recovery after the induction of premature labour —Dr WILLIAMSON considered that under the term eclampsia they grouped together at the present time conditions which had very little in common with one another On the one hand there was a well marked group of cases in which the patients were the subjects of chronic nephritis. In these patients what they termed eclampsia was really a uræmic condition and though modified by pregnancy still it differed in no essential from uræmia occurring in a non pregnant woman But there was another and an entirely different class of case in which the convulsions appeared to depend upon an acute toxic poisoning the stress of which fell more especially upon the liver, and the kidneys might almost escape damage. In support of this contention he quoted a case recently seen in which 40 eclamptic fits occurred within 24 hours of delivery The urine was not reduced in amount the percentage of urea never fell below 1 6 per cent. only a slight cloud of albumin was present, and no tube casts were found After the cessation of the fits however the patient became deeply jaundiced and bile was found in the urine The patient recovered

Mr ALBAN H. G DORAN exhibited a Retro-peritoneal Lipoma, weighing 13 pounds 12 ounces removed from a woman aged 47 years. The omentum was not involved. The right kidney lay on the pelvic brim in a lobe of the tumour which was supplied with blood by large vessels arising close below the pancreas. The patient rallied from the operation but died 38 hours later from suppression of urine. Mr Doran noted that surgically this kind of tumour must be distinguished from the purely omental type (Meredith and perhaps Lannander) and from lipoma of the broad ligament (Treves) varieties which allowed of easy and safe removal. The results of extirpation of these absolutely retroperitoneal lipomas were very unsatisfactory Ferrier and Guillemain questioned on good grounds whether it was justifiable to attempt their removal when their nature was recognised at an exploratory operation.—The PRESIDENT Dr CULLINGWORTH Dr HERBERT R. SPENCER, and Dr GILES took part in the discussion

Mr J W TAYLOR read the notes of a case in which delivery at full term had been obstructed by the presence of an Ovarian Tumour in the Pelvis. After considering the relative advantages of abdominal and vaginal ovariotomy it had been decided to make a posterior vaginal section and to perform ovariotomy during the progress of labour This was successfully accomplished and then delivery had been completed by the aid of forceps without delay The patient had made an easy and very satisfactory recovery —The PRESIDENT congratulated Mr Taylor on the happy termination of his case. But he could not help feeling that he had been lucky in finding this ovarian cyst so simple and so free from adhesions. Had it been a multilocular cyst with myriads of small cysts had there been a lot of adhesions extending to the bowel, or had the pedicle been difficult to reach he might have been obliged to open the abdomen after all He related details of a case in Guy s Hospital where a tumour occupied the pelvis and obstructed labour It was under such great pressure that *it was thought to be a solid tumour* There was no fluctuation and it felt a hard as any fibroid A needle was pushed in and pus was withdrawn. Then an incision was made and a loculus was emptied a septum was punctured and another loculus was emptied and then a third one, after which it was found possible to deliver Subsequently another loculus of this multilocular suppurating ovarian tumour opened and discharged near the navel and the patient left the hospital and was lost sight of After trying operations per vaginam he must say that he preferred to tackle these tumours through the abdominal wall One great danger was the pedicle which sometimes tore when being pulled down in order to reach it from the vagina.—Dr SPENCER thought that abdominal ovariotomy was preferable to vaginal ovariotomy in the treatment of these cases Mr Taylor seemed to have chosen vaginal ovariotomy partly because he would probably have to evacuate the pregnant uterus or do a Cæsarean section before he could get at the imprisoned tumour" It could not be too strongly insisted upon that Cæsarean section was quite unnecessary In Mr Taylor's case the tumour, which he understood contained two or three pints, would certainly have reached above the brim of the pelvis and might have been opened there possibly without much difficulty But in any case by enlarging the incision (and it was surprising through how small an incision the pregnant uterus would pass if taken out one cornu first) the tumour could have been easily dealt with, and then forceps could have been applied and the uterus returned. The vaginal operation appeared to him (while having some slight advantages alluded to by Mr Taylor) to be, on the whole, inferior in that it made a wound in the vagina but did not permit inspection of the other ovary or allow of such careful treatment of adhesions or of the pedicle Mr Taylor had himself found difficulty in dealing with the pedicle in that he had tied it by encircling it with a ligature applied beyond a pair of forceps and had to cut the ligature short by the sense of touch This appeared to him to be not free from danger of slipping of the ligature Cases had been recorded of slipping of the ligature and such cases showed the necessity of careful separate ligation of the ovarian vessels in the pedicle in cases of ovariotomy during pregnancy, which could only be satisfactorily performed by the abdominal operation —Dr **Heywood Smith** said that about 17 or 18 years ago he had a similar case under his care He tapped the ovarian cyst per vaginam and delivered the woman It was not till she was between three and four months pregnant again that she presented herself. He then did ovariotomy during the pregnancy, the patient did well, went her full time, and subsequently had other children.—Dr M **Handfield-Jones** recorded two cases of suppurating dermoid tumour which had obstructed delivery at full term In both cases he had thought it best to open the abdomen and remove the tumours by the abdominal route While performing these operations he had been struck by the difficulty which would have been encountered if he had endeavoured to effect the removal by the vaginal route, for in both these instances the upper wall of the tumour had been densely adherent to coils of small intestine, and great risk of tearing the bowel would have arisen if an attempt had been made to withdraw the growth through an opening in the vagina. The plan of removing the tumour by the abdominal route and then replacing the pregnant uterus and effecting delivery by the natural passages commended itself to him as by far the safest and most scientific procedure He thought that Mr Taylor was to be congratulated equally on the success of his operation and the good luck which had attended it —Mr **Taylor**, in reply, said that while acknowledging the good fortune for which every surgeon should be grateful he wished the Fellows to understand that the operation was deliberately chosen and that this choice was made in consequence of an experience of vaginal cœliotomy extending now over some nine or ten years, during which he had repeatedly removed small ovarian cysts, diseased tubes, small dermoid tumours and extra uterine pregnancies by the vaginal method As experience widened it could be generally judged what cases were suitable for vaginal section and it was only in the minority of cases (possibly some 5 per cent.) that an operation begun by the vaginal had to be finished by the abdominal route. Even when this was necessary he had found that the additional vaginal opening was no disadvantage, being often exceedingly useful for drainage The chief difficulty of the vaginal operation was undoubtedly the comfortable securing of the pedicle but (as a previous speaker had already stated) the surgeon could leave a pair of forceps on the stump, if necessary, with perfect safety In addition, the open method of treating the vaginal wound (with an iodoform gauze drain) precluded the possibility of any serious hæmorrhage occurring without the immediate knowledge of those in attendance. As Dr Spencer was describing his case (requiring a large abdominal incision, eventration of the pregnant uterus, and delivery of the child while the uterus was still outside of the abdomen) he could not help unfavourably contrasting the operation as described with the simple, direct, and comparatively easy method employed in his own case. Moreover, in his own case the patient recovered with no abdominal wound or cicatrix In the other operation a large wound was made and if this were closed hurriedly (a proceeding almost unavoidable under bad surroundings) a hernia of the cicatrix was extremely likely to develop later He would in no case use simple puncture or aspiration by the vagina. The danger of fouling the peritoneum by oozing from a pus sac or dermoid cyst contra indicated this practice, and in every case that recovered an operation had to be done later The method described, Mr Taylor believed, formed a legitimate and very useful extension of operative practice which, in suitable cases, satisfied the requirements of good surgery much better than did the more usual method of operation by abdominal incision

OPHTHALMOLOGICAL SOCIETY

Detachment of the Retina —Convergent Strabismus —
Exhibition of Specimens

An ordinary meeting of this society was held on July 4th, Mr **Charles Higgens**, Vice President, being in the chair

Mr **Higgens** described a case of Detachment of the Retina in which complete recovery took place The patient was a woman, aged 36 years, who had been under his care since 1892 for myopia of high degree and had in 1899 nearly lost the sight of the left eye from detachment of the retina. In May, 1901, she first noticed obscuration of the upper part of the field in the right eye There was a doubtful history of injury some weeks before Detachment of the retina at its lower part was discovered. She was treated for nearly a month in hospital, lying in the prone position, with mercurial inunction and vapour baths, and she left with some improvement. Two weeks later her sight returned whilst lying down in the afternoon she went to sleep for some hours and on waking found the sight as good as it had been before the detachment occurred Ophthalmoscopic examination showed some floating shreds in the vitreous but no sign of detachment On Jan 23rd, 1902—nearly nine months since the detachment appeared and eight months since the recovery of vision—she could see with correction $\frac{6}{24}$ and J 1. The field was almost normal and there was no sign of detachment.

Dr E H. **Cartwright** also read notes of a case of Detachment after Cataract Extraction The patient was a man, aged 72 years, who had had a cataract removed from his eye without iridectomy in February, 1899 Subsequently two capsulotomies had been done In April, 1900, Dr Cartwright first saw him and with his correction he could read $\frac{6}{6}$ and J 1. In January, 1891, he again attended with the history that two weeks previously the sight of the right eye had suddenly failed late one day, everything looked at appeared red and the sight was lost below the horizontal meridian. The sight had got gradually worse since. The vision in the upper part of the field was equal to counting fingers at six inches Left vision = P L Almost complete cataract was present. Projection was good In the right eye the upper half of the retina was detached and this obscured the view of the disc The urine and heart were normal. The patient was kept in bed and on Jan 9th a scleral puncture to the outer side of the superior rectus tendon as far back as possible was made and from this some clear watery fluid exuded On Jan 25th the disc was visible but vision was not improved. After this he was discharged but was seen from time to time with gradually improving vision until in September, 1901, he could read $\frac{6}{18}$ and J 2. The field was normal except on the temporal side On Sept. 27th, 1901, the left cataract was extracted and on Nov 29th, 1901, his vision was as follows with correction right vision = $\frac{6}{12}$ and J 1, left vision = $\frac{6}{6}$ and J 1 —Mr N M **Maclehose** mentioned a case which he had seen of detachment due to a blow in which recovery had taken place —Mr G **Hartridge** thought that the experience of Mr Higgens and Mr Cartwright was exceptionally good, for he himself had never seen a case of such complete recovery —Mr **Jessop** remembered only one case in which recovery had resulted and this was reported by Mr E Nettleship and Mr J Tweedy to the society some years ago He had seen temporary improvement but it never lasted.—Mr C **Devereux Marshall** said that the only case of complete recovery which he knew was the one referred to by Mr Jessop In a case which he had had, where in the second eye the retina had become detached, a good result was obtained, and this lasted for several months but it recurred and the patient became quite blind He also remembered another case, due to a blow, in which the retina became re attached, but as he had been unable to trace the patient after the first few weeks following the accident he had not thought it well to publish it as a cure.—Mr HIGGENS, in reply said that he doubted very much whether the treatment adopted in his case had anything to do with the recovery of vision.

Mr SYDNEY STEPHENSON read a note on some cases of Convergent Strabismus treated by lengthening the tendon of the internal rectus and exhibited the patients. The method adopted was that of cutting the tendon of the muscle either obliquely or in some other manner by means of which the cut ends could be united in such a way that the muscle was thereby lengthened to the required degree. He had operated upon six cases with gratifying results.—Mr. HIGGENS thought that this method was likely to be of considerable benefit.

The following card specimens were shown —

Mr J H. PARSONS (1) Gumma of the Ciliary Body, (2) Metastatic Carcinoma of the Choroid and (3) Annular Leuco-Sarcoma of the Ciliary Body

Mr R. W DOYNE Rupture of the Eyeball with Prolapse of the Iris and no Dislocation of the Lens

---

DERMATOLOGICAL SOCIETY OF LONDON —A meeting of this society was held on July 9th Dr J J Pringle, being in the chair —Dr T Colcott Fox showed a private patient who was suffering from Generalised Alopecia. The patient was a young man in perfect health but of a somewhat nervous disposition, and no cause for the onset of the disease had been discovered. The history showed that five years previously a single spot of alopecia areata had occurred on the right side of the chin before which the patient said that he had had a very 'ugly pimple' in the same situation and lasting several weeks When shown the head was almost entirely bald only a few small tufts of dark hair remaining here and there. There was a bald patch in the centre of the right eyebrow and most of the hair of the face had gone. The patient was naturally a very hairy man and consequently the patches of baldness which were observable on the chest, the hypogastric region, and the upper part of the calf were very striking and sharply defined. Dr Colcott Fox said that he exhibited the patient for two reasons—first, because although alopecia universalis developing from alopecia areata was not very uncommon it was not often that the opportunity was had of observing the actual round areas on the trunk and limbs and secondly he thought it of interest that, although on the scalp and to a certain degree on the face the oily condition and follicular plugs of Sabouraud could be demonstrated, on the trunk and limbs no trace of any seborrhoeic progress could be detected —Dr G F Still and Dr A. Whitfield showed a child a little more than a year old suffering from a Bullous and Hæmorrhagic Eruption. The history was rather indefinite, the mother stating that the child had had an eruption of blisters in the first week of its life. The present eruption had existed for a little over five months, thus leaving a period of entire freedom of about seven months. The child seemed to be quite well, but owing to the intense itching of the eruption at night its sleep was often much broken. The eruption was distributed over the whole trunk and extremities sparing the face entirely and falling with greatest severity on the buttocks, the extensor surfaces of the knees and elbows, and the hands and feet. The rash was extremely polymorphous. On the elbows and knees were large hæmorrhagic bullæ reaching to the size of an acorn and in addition to these there were a good many small vesicles. The whole of the outer surface of each thigh was thickly set with a fine papular eruption consisting of millet-seed-sized papules with a flat and shining top. On the loins and buttocks there were large thumb-nail-sized erythematous macules with a dark and firm papular centre. On the hands and feet were small lichenoid papules and pustules and scabs. In addition to this, when first seen there were two scratch marks which were mapped out by the formation of a line of small vesicles, but these had flattened down. The mucous membranes were not affected. Dr Whitfield said that he thought everyone would agree with his diagnosis of lichen urticatus for the lesions of the maculo-papular type and the scratch marks. The question was whether there was anything beyond this. He reminded the members that the demonstrations and writings of Dr Colcott Fox had made them all familiar with the occurrence of bullæ in lichen urticatus, but he had never seen a case resembling the present one. The idea had occurred to him that the child might be the subject of epidermolysis bullosa, and he could not definitely exclude this. On the whole, however he felt inclined to believe that this was not present for the reason that the child had had apparently an immunity lasting for seven months, during which time no blisters had appeared.—All the members agreed as to the presence of the lichen urticatus but as to the coincidence of two diseases no one liked to offer an opinion.—Dr Colcott Fox pointed out that in his experience the bullæ in lichen urticatus were almost invariably situated on the hands or feet.—Dr Pringle showed 1 A child aged three years, suffering from a Relapsing Bullous Eruption. The eruption had appeared first in September 1901, and had disappeared in May, 1902 reappearing in June. On exhibition the child showed a generalised eruption which commenced as small pearly vesicles. The original vesicle flattened down and became surrounded by a new ring of similar lesions, and by the continuation of this process large circles and polycyclical figures were produced. The mucous membranes were unaffected and there was no itching In spite of this absence of itching Dr Pringle offered the diagnosis of dermatitis herpetiformis which all the members accepted 2. A young man suffering from a Miliary Papulo-pustular Eruption The history was that the man had had a sore on the penis seven weeks previously the sore appearing one week after connexion lasting two weeks, and disappearing under local antiseptic treatment only Slight adenitis had appeared in one groin but had gone down completely at the time of exhibition. On the other hand the patient had suffered for some time from tuberculous adenitis in the neck, and recently some of the glands had suppurated and had been surgically treated at Middlesex Hospital. At the time when he was presented to the society he showed an eruption of fine, purple, firm papules, each in most cases being surmounted by a minute pustule. The eruption was situated at the pilo-sebaceous follicles and distributed chiefly on the extensor surfaces of the upper arms and over the shoulder blades. The case was brought forward to show the difficulty in view of the complicated history of distinguishing the syphilide from the tuberculide, and Dr Pringle asked if any of the members would tie themselves down to a definite diagnosis —There was a great deal of discussion and although most members inclined to the view that the disease was in all probability syphilis few cared to commit themselves to an absolute opinion.—Dr J Galloway brought forward a woman aged 36 years, in apparently good health who showed a peculiar line of Telangiectases across the chest and back at the level of the fourth dorsal vertebra, above which there were slight thickening œdema, and pigmentation of the skin The fingers of both hands were uniformly thickened and very hard the whole process being essentially chronic in its progress.—The relationship of the disease to scleroderma was discussed and the whole case was admitted to be entirely anomalous in its characters —Dr Whitfield suggested that the hands should be radiographed as the sensation given to the fingers was that of a true barrel shaped enlargement of the phalanges, and he reminded the members that a case had been published by Mr C. B Lockwood in the Transactions of the Clinical Society of London (1897) in which there were features somewhat resembling this case.—Dr H Radcliffe Crocker brought forward again a man shown at the April meeting suffering from Lupus Erythematosus of the face and hands. The patient was exhibited again to show the effect of the administration of salicin in 20-grain doses three times a day under which treatment all the infiltrated erythema had subsided so that it could hardly be said that any active disease still existed.—Dr E. G Graham Little showed a baby seven months old exhibiting a good example of the Annular Syphilide. The signs of the disease had first appeared one week previously to exhibition and consisted of several small infiltrated rings of about the diameter of a sixpenny piece, situated on the anterior and internal surfaces of the thighs. On the posterior surfaces of the thighs were some large lenticular syphilitic papules, and there appeared to be condylomata commencing round the anus. The history given at first was that the child had had no rash before this one but closer questioning revealed the fact that there had been scaling of the palms and soles, which still showed a similar condition, soon after birth.—Dr J H Sequeira showed a man aged 74 years, with an Ulcer of the size of a florin on the Back of the Neck. This ulcer had existed for 26 years and was of a bright red colour with slightly everted and somewhat infiltrated edges. There was a large, hard gland on the right side of the neck, rather higher than might have been expected, in connexion with the growth. The diagnosis offered was that of a slowly growing malignant ulcer of epithelial type, but whether rodent ulcer or epithelioma neither Dr Sequeira nor any of the members cared to state definitely The growth would be removed and reported upon.—Dr Sequeira also showed a classical example of Xerodermia Pigmentosa in a little girl, aged five years Pigmentation had been noticed at the age of 10 months and a wart been removed from the face when the child was three years of age and two more after she had reached her fourth year When shown the skin of the face was generally atrophic and was marked by numerous freckles and small telangiectases There were also two large warty growths on the left side of the bridge of the nose with pearly rolling edges, suggestive of burrowing of the epithelium. These would be removed and reported on later —Dr S E Dore showed three cases of Psoriasis following vaccination In one case the attack was the first from which the patient had ever suffered, in another attacks had occurred before, and in the third the history was doubtful All the patients were adults and in all the rash had started immediately after the healing of the vaccine vesicles, appearing at the sites of the lesions first

NORTH-EAST LONDON CLINICAL SOCIETY —This society held its annual general meeting at the Tottenham Hospital on July 3rd, Dr F J Tresilian, the President, being in the chair —The report of the council and the treasurer's report were read and adopted —The following gentlemen were elected officers of the society for the session 1902–3 President Dr F H. Daly Vice Presidents Dr C T Aveling, Mr Walter Edmunds, Dr F de Havilland Hall, Mr J Langton, Dr E Hooper May, Mr J S Sequeira, Dr T Gilbart Smith and Dr F J Tresilian Honorary treasurer Dr Arthur E Giles Council Mr C Billson, Dr G P Chappel, Dr H Corner, Dr S E Dore, Dr J W Hunt, Dr R. Murray Leslie, Dr G Norman Meachen, Dr D Petty Dr A. S Ransome, Mr R. F Tomlin, Dr A. J Whiting, and Dr C H Wise Honorary secretaries Mr H. W Carson, 26, Welbeck street, W , and Mr C E Hutt, Bruce grove, Tottenham, N —After the meeting tea was served in the grounds of the hospital to a large number of members and their friends, the presence of ladies adding much to the success of the proceedings

Reviews and Notices of Books.

Sewage and the Bacterial Purification of Sewage By SAMUEL RIDEAL, D Sc Second edition London The Sanitary Publishing Co , Limited 1901 Pp 308 Price 14*s*

THE remarkable development of the bacterial treatment of sewage has soon rendered new editions of standard books upon the subject necessary Dr Rideal's excellent treatise appeared in the press early in 1900 and hardly a year passed before he felt compelled to prepare a second edition, not only on account of the rapid sale and early exhaustion of the first edition but because our knowledge of the bacterial processes both in theory and in practice has advanced considerably in that short period. The statement of principles such as those of the stages of purification remains, of course, the same since the conditions essential to the disposal of sewage by wet combustion are now understood. Effectual, however, as the mere destruction of effete organic matters may be, the question is still open as to whether pathogenic organisms lose their vitality or even suffer a diminution in virulence under the conditions prevailing in a biological filter It is well known that Dr A. C Houston, at the instance of the London County Council, has made some interesting experiments upon this point. From his results as a whole he was not able to say with certainty that in the cases of the typhoid bacillus and the cholera vibrio they would lose their activity a whit, or that the biological processes at work in the coke beds would produce any significant alteration in the number of spores of the bacillus enteritidis The bacillus coli is similarly unaffected, but, as Dr Rideal points out, though classed as pathogenic this organism can hardly be considered to be so in the ordinary sense of the term Its presence, however, as Dr Rideal does not omit to add, serves as an index of the possible presence of other and more objectionable kinds of bacteria. Certainly, as regards the experimental beds at Barking and Crossness it cannot be assumed, according to Dr Houston's results, that the effluents are more safe in their possible relationship to disease than is diluted raw sewage Of the chemical purification effected there can be no doubt that it is sufficient to reduce entirely all putrefactive matters Dr Rideal points out that in Dr Houston's experiments the degree of nitrification and aeration was never pushed to a satisfactory point and the conclusion seems to be warranted that the greater the aeration and nitrification the less is the possibility of the survival of pathogenic organisms Dr Rideal states that subsequent chemical treatment could be used for sterilising filtrate if necessary Such reagents, he suggests, might be called "finishers," for by their employment the resulting purified sewage would be satisfactory both from the chemical and bacterial points of view We assume that the ' finisher" would be employed in such a small quantity as not to interfere with river life

The second edition of Dr Rideal's eminently practical work was issued just before the interim report of the Royal Commission on Sewage was presented to Parliament in July, 1901. The most remarkable and important conclusion in this report was that ' there are cases in which the Local Government Board would be justified in modifying under proper safeguards the present rule as regards the application of sewage to land " Dr Rideal regards—and we ourselves have expressed the same view—the insistence on final land treatment as decidedly a mistake when the object is only purification As is well known, it frequently happens, as in the case at Hampton (Middlesex), that an originally good effluent suffers great deterioration by subsequent passage through land

Dr Rideal's book will be studied with advantage with regard to both the practical and theoretical aspects of the subject and an excellent and sound idea of the present position of bacterial methods of purification of sewage will be gained by a careful perusal of its pages It is undoubtedly a standard work.

Hygiene a Manual of Personal and Public Health. By ARTHUR NEWSHOLME, M D , F R.C P Lond , Medical Officer of Health of Brighton, &c London George Gill and Sons, Limited. New edition 1902 Illustrated Pp 356 Price 4*s* 6*d*

THE first edition of this work appeared so far back as 1884 and naturally in preparing a new edition there was a great deal that needed altering As the book contains much that is of great practical use, presented in a form and manner admirably suited for ready reference, it was very necessary that this store of information should be brought up to date Indeed, the present edition has been almost entirely rewritten and a considerable amount of new matter has been introduced, notably in regard to dietetics, trade nuisances, meteorological observations, tuberculosis, disinfection, and vital statistics For instance, one of the recent points raised is Professor Koch's contention that bovine tuberculosis is not communicable to man. This question, Dr Newsholme very correctly states, is not yet settled and in the meanwhile he considers that the ideal would be to condemn all cattle suffering from tuberculosis But this involves a serious economical problem and in practice it is not customary to condemn the entire carcass when only one organ is affected The pig however, should always be condemned because of the greater tendency of generalisation of tuberculosis in that animal Because man cannot infect cattle it does not follow that cattle cannot infect man and Dr Newsholme urges that no tuberculous animal of any kind should be allowed to remain in any cowshed where milch cows are kept." That such measures are necessary and not properly applied is shown by the fact that the proportion of infected samples found when examinations of milk-supplies have been made in different towns has varied from 10 to 50 per cent. But, fortunately, it is not necessary to boil milk to destroy the tubercle bacilli and the Danish law of 1898 compels every dairy proprietor to heat his skimmed or butter milk, but only to 185° F A description is given of various apparatus and methods for sterilising milk. In this manner about 60 of the principal problems of hygiene are treated and discussed. A large number of illustrations very materially help to render the meaning clear Indeed, in such matters as drainage, especially for a beginner who has not yet acquired practical experience of the meaning of technical terms, illustrations are indispensable. Altogether Dr Newsholme is to be congratulated on the new issue of his book and it will be a welcome addition to the library of the student of hygiene

Practical Lip-reading By E. F BOULTBEE. London L. Upcott Gill. 1902. Pp. 112.

THE subject principally dealt with in this little work is the value of lip-reading for persons who have the misfortune to become deaf or partially deaf in adult life the book is very interesting and deals with a somewhat new adaptation of educational endeavour to benefit the large number of adults who being deprived of hearing find themselves to some degree excluded from the ordinary resources of social life In such cases it is desirable that the patient should learn to read at sight the expression of speech on the lips of the speaker In the child all speech is acquired by imitation, either through the eye or the ear and, therefore if the child be totally deaf the teaching must necessarily be conducted through sight but if there is a remnant of hearing the ear doubtless helps. The author divides the teaching of deaf children into four stages (1) from babyhood to the time that he is brought under proper control in order to fit him for instruction and can be made to look at the teacher's mouth (2) the development of articulation and production of sounds (3) the connexion of certain movements of the lips with the objects and action which they represent (this embraces the teaching of language at this stage it is desirable to make the child repeat the question put and then to give the answer) and (4) the ordinary school curriculum, including careful culture of the powers of observation The child who is born deaf must be taught the use of language through sight the adult who becomes deaf starts with the faculty of speech and knowledge of the use of words but to be impressed by the sight of the words of the speaker as formed on the lips careful training is required. It is necessary that the teacher should have a complete knowledge of the art of lip-reading—an accomplishment to be acquired only by long study and experience. The adult pupil must be trained in seeing in order that he may rapidly recognise and appreciate those positions and movements of the tongue and the lips which are required when a speaker gives forth the sounds which are represented by letters and which when strung together form the spoken word It is then necessary that the student of lip-reading should study the lips of the reader rather than the eyes Efficiency in the art of lip reading may be acquired by deaf adults and this mainly depends upon the way in which the facilities of observation and perception of movement have been cultivated, together with readiness of mental inference as to the meaning Those persons who become deaf in middle life are apt to find themselves isolated Some of the cases narrated by Miss Boultbee show that ready intercourse in social life may be re-established by acquiring the art of reading words and sentences from the speaker's face. The subject is an important one and the training suggested, if followed out with perseverance is likely to ameliorate the condition of those who have lost their hearing Besides the technicalities of training explained in this book there are many hints given which are likely to be appreciated by deaf persons.

LIBRARY TABLE

Hare-lip and Cleft Palate By R. W MURRAY F R.C S Eng London J and A. Churchill. 1902. Pp. 34 Price 3s —Mr Murray who is surgeon to the David Lewis Northern Hospital Liverpool was formerly surgeon to the Liverpool Infirmary for Children so that he has good opportunities of becoming acquainted with the subjects about which he writes in the book before us. He points out, and we think with justice, that there are few operations in surgery in which it is so difficult to secure a good result as that for hare-lip. His experience with regard to the matter consists of 168 cases of hare-lip most of which included a cleft of the palate. Mr Murray gives details of the methods employed by him which are very clearly set out and are further illustrated by diagrams. The book will be found to be thoroughly useful and practical.

Malarial Fever its Causes Prevention and Treatment By RONALD ROSS, C B F R.S. &c Published for the University Press of Liverpool by Longmans, Green, and Co. London 1902. Pp 68. Price 2s. 6d.—This book forms Memoir No 1 of the Liverpool School of Tropical Medicine Being written mainly for the use of travellers soldiers, and residents in malarial countries it does not go into scientific detail but states in plain and simple language how malaria is conveyed and communicated how it may best be avoided, and how if acquired it may be treated by a layman in the absence of medical aid. The treatise will be found most useful and everyone proceeding to a malarial country should take a copy with him

The Prevention of Infection in Public Vehicles By ALFRED GREENWOOD M D Vict. London The Sanitary Publishing Co. Limited. 1902. Pp 65. Price 1s net.—This little book is practically an expansion of a paper read by Dr Greenwood at the congress of the Royal Institute of Public Health which was held at Eastbourne in 1901. In our issue of Oct 5th 1901 p. 927 we endorsed Dr. Greenwood's suggestions as to the cleansing of public vehicles and we can but repeat our endorsement. A Minister of Public Health is a much needed addition to Government.

Transactions of the Childhood Society for the Study of the Mental and Physical Conditions of Children London Childhood Society 1902. Pp. 88. Price 2s 6d.—This is the first volume of Transactions issued by the Childhood Society and it appropriately commences with a portrait and a notice of the work of Sir Douglas Galton K.C B F R S as founder and first chairman of the society As a sanitarian and earnest scientific worker he was early impressed by the evidence accumulated during the examination of 100 000 children seen in schools and their variations in development as found in different urban and rural districts. The society was established to study conditions of mental and physical development of normal children as well as of those whose conditions are abnormal or who are feebly gifted mentally Its existence has been more than justified by the useful work done it fills a public need and has afforded guidance and helped to educate public opinion with regard to many educational and philanthropic movements while on several occasions evidence and recommendation have been given to Royal Commissions and other public bodies concerning special classes of children and their requirements Abstracts of the following lectures which were delivered during the past year are published on Food Dietaries in Relation to School Life, by Dr R. Hutchison, on Observations of Children after the Methods of Natural History, by Dr Francis Warner, and on a Method of Teaching Children to Read, by Mr M. Friedeberger, Ph.D Two useful and interesting discussions were held, that on School Discipline from the Scientific, Inspector's, Teacher's, and Hygienic Points of View was introduced by Mr A. W Newton, M.A., and that on the Practical Bearings of the Society's Investigations on Social Questions by Mr E W Brabrook, C B These showed how great is the need of widespread and exact knowledge of childhood Two prizes were offered to teachers, for essays on Suggestions as to Giving Effect to the Education Code and on Children considered Suitable for Special Instruction, for these there was a keen competition. The volume gives much interesting information to those engaged in the care of children and their education

Report on a Visit of Inspection to Colonies and Hospitals for Epileptics, the Feeble minded, and the Insane in the United States of America By J MILSON RHODES, M.D Brux., and EDWIN W MARSHALL, C A. London P S King and Co 1902. Pp 51.—Dr Rhodes and Mr Marshall were sent as a committee of inquiry by the committee of the proposed colony for epileptics to be established at Warford, Cheshire Their mission was to become acquainted with the best method of management of such an institution. Colonies and asylums were inspected in the following States New York, Ohio, Pennsylvania, Maryland, and Massachusetts The opinions of the committee of inquiry may be shortly summarised by the following passage "The State of New York has fully realised the necessity for legislation in the interest of epileptics and has acted upon it. We are strongly of opinion that the sooner the authorities in England follow the example set by the State of New York the better it will be for the interests alike of the ratepayer and the unfortunate persons suffering from epilepsy"

Reports on Mosquitoes North Shore Improvement Association. New York Styles and Cash 1902. Pp 125 and a map—The "north shore" mentioned in this report is the north shore of Long Island and it is a district much troubled by mosquitoes Hence the North Shore Improvement Association, the objects of which are generally to promote "such measures as will tend to protect the territory as a desirable residential region," took the matter up The examination of the matter was entrusted to an engineer Mr Henry Weeks, two entomologists (Professor Charles Davenport and Mr F E. Lutz), and Professor Shaler, an eminent authority on marine marshes, places which are favourite breeding grounds for mosquitoes. The report is very interesting reading and, shortly summarised, it states that the breeding of mosquitoes can be prevented but that State legislation and the coöperation of the municipal authorities must supplement individual action.

A Hero of Donegal, Dr William Smyth. By FREDERICK DOUGLAS HOW London Isbister and Co 1902. Pp. 146 Price 2s 6d net—William Smyth was one of that noble army of medical men who have laid down their lives in the service of their fellows The story of how he and Dr Brendan McCarthy, an inspector of the Irish Local Government Board, rowed across a strait in a crazy old boat and, no man aiding them, removed certain patients stricken with typhus fever to the hospital, is fresh in everyone's mind The sequel of this act was that Mr Smyth, who was run down from hard work and anxiety, contracted the fever himself and died. Mr How tells the story of William Smyth's life and death in a simple unaffected fashion. It was a life such as few have the opportunity of leading and one, moreover, which perhaps still fewer would care to lead if they had the opportunity, but, like Abou Ben Adhem, William Smyth could be written down as one that loved his fellow men, and who shall say that he has not reaped his reward?

Lights and Shadows in a Hospital By ALICE TERTON London Methuen and Co 1902. Pp 229 Price 3s 6d—This is an easily and brightly written book Mrs Terton possesses two faculties which are of value to a writer—namely, observation and the grace of humour We gather that her experiences were obtained some years ago, but although nursing has changed, patients are all much the same and so are the types of people who visit in hospitals Of these two classes Mrs Terton gives many little life-like sketches and we can recommend the book to anyone who wishes to know something of hospital life apart from medical details

The Cult of Chiffon By Mrs ERIC PRITCHARD London Grant Richards 1902. Price 5s Pp 212—This is a book which the mere man feels a natural diffidence in reviewing Only recently a contemporary, in giving an account of Henley, began to describe the dress of the ladies After a line or two the writer broke off, saying that he remembered the fate of Actæon It is some time since we read the Metamorphoses, but, so far as we remember, Actæon's fate was connected with a lack of clothing rather than with an abundance thereof Medical men, however, have a licence forbidden to other men, so we may say that Mrs Pritchard's remarks upon clothing are eminently satisfactory both from the point of beauty and hygiene The average woman is apt to think that hygienic dress must be ugly, but a perusal of this book will show her that it is not so Most sensible are the writer's remarks upon athletic dress and upon the care of the complexion Miss Le Quesne's illustrations are charming, and great praise is due to the publisher for having included among the advertisements only one of a "beauty specialist."

IN our issue of Feb 1st, p 313, we reviewed at length the official account of the Surgical and Medical History of the Naval War between Japan and China during 1894–95 The copy of the book which we noticed was sent to us from Japan by the courtesy of Baron Saneyoshi, the Director-General of the Medical Department of the Imperial Japanese Navy As the book is valuable and likely to be referred to in the future we think that it is well to announce that it can now be obtained from Messrs Kegan Paul, Trench, Trübner, and Co, Limited, who have the sole market for England. The price is £1 11s 6d

New Inventions.

THE HELIX NEEDLE

THE "Helix" is a spiral or corkscrew shaped needle designed with the object of including the broad ligament in a continuous suture in the operation of hysterectomy The worm of the helix is grooved in order to carry a suture, the point is blunt and the eye is kite-shaped On threading the needle the suture is drawn into the narrow part of the eye and is thus prevented from slipping during the process of winding it on to its groove. This is done as follows—After threading the needle the suture is gently held in its groove by the thumb of the left hand which, as the helix is rotated, follows each spiral and so holds the suture in its groove. The groove terminates in a vertical slot, into which the suture is finally placed. The instrument is now ready for use, having a strand of suture held taut and lying in its groove. In using the needle the point is introduced close to the edge of the ligament and is firmly pushed through the tissues on to the forefinger of the left hand In this manner the helix is made to travel along the ligament, care being taken that whenever the point is being pushed through the tissues the left forefinger ascertains that it has passed completely through, otherwise there would be danger of the point passing between and not through the layers. The handle of the needle is then depressed so as to elevate the point and to bring it into position as much as possible. With an aneurysm needle the free end of the suture can easily be released from the tissues. The next step is the unthreading of the needle, and in order to facilitate this the groove is made to terminate half an inch from the eye, so that a pointed needle can easily take hold of the suture and draw it out of the eye. This was a suggestion made by Mr Down and adds greatly to the value of the instrument. The end of the suture thus freed is held in a pair of clip forceps while the helix is slowly withdrawn by rotating it in the opposite direction leaving the suture in its track. By pulling the free ends the suture is tightened and the tissues embraced by the suture are completely strangled. A portion of ligament is now included in a continuous suture, leaving two free ends yet to be dealt with. The distal free end is threaded to an aneurysm needle and carried by it through the tissues so that when unthreaded there is a loop and free end on the surface of the ligament, these are made into a firm knot. The suture is again tightened by pulling on the remaining free end. All that remains to complete the operation is to deal with the proximal free end in the same manner except that the pedicle needle is first carried round the edge of the ligament.

Honorary Surgeon Huddersfield Infirmary

A SUTURE SICKLE.

THE removal of sutures in some situations, and especially in cavities, is sometimes a matter of difficulty To simplify the procedure I have devised an instrument in shape something like a short aneurysm needle on a long handle. The concave edge is, however sharp and the point is blunted like a small probe. It is an easy matter to pass the probe-point under a suture and to cut through with a slight jerk and only one hand is required. The sickle will be found a convenience for removing sutures from the uterine cervix, since the slender instrument in the speculum does not obscure the light and no forceps or scissors are required. I have also found it to simplify the removal of stitches in the perineum and on skin surfaces generally Dr C Lawson Smith resident medical officer at the Tottenham Hospital, has found it to answer well for general surgical cases. Messrs. Mayer and Meltzer who make the instrument, have carried out my idea very satisfactorily

FROM

THE LANCET, *SATURDAY, JULY 17*, 1824

The pre-disposing cause of scrofula is congenital, or original fault of constitution. The exciting causes are whatever tend to produce, or rather increase that debility, such as the fever from diseases of a specific kind as measles, scarlet-fever and small pox. Scrofulous affections occurring after small pox used to be much more frequent before the introduction of vaccination than since, and if there were no other advantage attending it than this, it ought to be regarded as a boon to society The reasons, you must be acquainted with, how small pox disposes to the excitement of scrofulous inflammation without my entering into them at present.[1]

We consider it our duty to censure improper practices wherever we find them and we are really astonished to see the admission of persons into the wards of this hospital[2] tolerated who vend green gooseberries, unripe cherries and every other thing that a sick person should not have tempting those to purchase who know no better and affording the opportunity to others who from a vitiated appetite, regardless of the consequences, need no persuasion to do so. It should be recollected also that there are many children in the wards who are always anxious to lay out the little money their friends may furnish them with in the first trash that is shown them. The result with them almost invariably is a considerable irritation of the lining membrane of the stomach and bowels, and sometimes even amounting to inflammation with a corresponding constitutional disturbance, and we must not suppose that even adults can escape with impunity We have often observed great surprize manifested by the surgeon on finding the medicine which he had ordered produce just the opposite effect to that which was anticipated which has induced him to substitute a less efficient remedy under the supposition that the former one has disagreed with the patient. By which circumstance it happens that the patient is not only losing his time, but the surgeon is also losing confidence in the remedies he employs. We beg therefore, to direct the attention of the proper authorities to this point, in order that it may be prevented for the future. We have before had occasion to notice this practice and for a time it was discontinued. A repetition of the occurrence, has rendered a repetition of the caution necessary and we hope that this gentle reminiscence will not be without its effect.

LONDON SCHOOL OF MEDICINE FOR WOMEN — On July 11th at 40 Hunter street, W C. the prizes won by the students of the London School of Medicine for Women were distributed by Mrs Percy Sladen The St. Dunstan scholarship given by the governors of the Endowed Charities of St. Dunstan s-in the-East, value £60 a year for three years was awarded to Miss Somner the Singleton scholarship value £95 to Miss Coupland and the Mackay prizes of £20 each to Miss Bolton and Miss Payne. In referring to the work of the school during the past year Mrs Garrett Anderson dean of the school, who presided remarked that financially they were still in debt with regard to the new building but they hoped in a short time to succeed in sweeping the debt away During the year they had reduced the debt by £1500 and there wa now left to be cleared off about £6000. The most important event of the year was the appointment by the Royal Free Hospital Committee of women to two of the resident posts at the hospital These posts had been filled with conspicuous success. With regard to the South African Hospital Commission it was interesting to know that two of their past students, Miss Waterston and the Hon. Ella Scarlett, formed part of the commission and did exceedingly good and valuable work

The Illness of the King

SINCE we last wrote His Majesty the KING has continued make uninterrupted progress towards recovery So far, deed, has he travelled along the road to health that on uesday, July 15th, he was able to leave London for ortsmouth whence he went on board his yacht There is, deed, but little to add to what we said last week concerning His Majesty His condition is eminently satisctory and the wound is filling up surely if slowly As a atter of fact, the freedom from State care and social ties, together with the enforced rest in bed, has had a ost beneficial effect and the KING is looking better than has done for some years

He has all along been a most exemplary patient and spite the hot weather has slept well, not merely by atches but for continuous periods of eight or nine hours r FREDERICK TREVES and SIR FRANCIS LAKING, together ith two nurses, are with His Majesty on board the yacht lthough it might be supposed that recent State events ould have exerted a retarding influence upon His Majesty's onvalescence, yet we are enabled to state that neither the ception of Lord KITCHENER nor the personal interviews ith Lord SALISBURY and Mr BALFOUR, which were necestated owing to the resignation by the former of the remiership and the acceptance of that office by the latter, ad any bad effects Should the present fair weather connue it is only reasonable to hope that the fresh breezes f the Solent will accelerate the recovery so auspiciously egun in London.

An Indian Prince and the London Hospitals

THE announcement that His Highness the Maharajah f JAIPUR has given a sum of £5000 to King EDWARD'S Hospital Fund for London illustrates in a striking manner he closeness with which East and West are linked together under the sway of the King Emperor, while it affords an instance of the interest which the feats of surgical science excite among men of all ranks and nationalities when their attention is called to them by any notable example That the King of England and Emperor of India should have at all times taken a keen interest in, and been active to help, the hospitals of his metropolis, that he should on the day appointed for his Coronation have lain in his palace owing his life to surgeons who acquired their skill and perfected their discoveries in those hospitals, and that every detail of his danger and of the steps taken to avert it should have been known and eagerly studied by his humblest subjects who openly expressed their trust in the skill of the surgeons employed and their confident expectation of the successful issue which has since been vouchsafed,—are facts well calculated to impress the mind of an intelligent and enlightened oriental magnate He would well understand the part which is played by hospitals in securing the health of the community, while the Fund instituted by the KING himself would present itself as an obviously suitable subject for a gift complimentary to the monarch and acceptable in the eyes of his people Moreover, the Maharajah of JAIPUR will have learnt, if he has inquired, that, conspicuous among English institutions, our hospitals are open to the poor of all nationalities and religions and that many of the natives of the great continent in which his dominions lie have from time to time found admission to them as patients He will also be aware that to all parts of the British empire surgeons and physicians trained in British hospitals find their way

In India the field which is slowly opening to medical science is, of course, enormous Epidemic outbreaks of disease upon a scale of which in Europe we have no conception are there the incidents of ordinary seasons, officially chronicled but otherwise not calling for special attention. The recent epidemic of plague in India was conspicuous owing to the fierce nature of the outbreak and to the immunity which, with the exception of certain districts near the Himalaya mountains, the country had long enjoyed from *pestis bubonica* The epidemic also served to call attention to the difficulty of supplying effective medical and sanitary aid in a country lying under the restrictions of the rules of caste, so that it had a political importance of grave significance Cholera and small pox can be studied in India at any time by those who are interested in their pathology and treatment but who might find it difficult to secure subjects for observation at home It is not necessary to multiply instances such as these or to call attention to malarial fever and to recent efforts of science to cope with it, but it is easy to see that a native of India, ruler of a territory such as that in which the Maharajah of JAIPUR holds sway, would find during a visit to London much that would draw his attention to the science typified and localised in London hospitals The care and attention bestowed upon sanitary science in London, including its minuter details are conspicuous novelties in the eyes of princes coming from places far less distant from centres of European progress than Jaipur To an Eastern prince it should be a fact of considerable interest that a town containing between 4,000,000 and 5,000,000 of inhabitants can exist in complete ignorance of epidemic disease as it is understood in India. The circumstances which beset the practice of sanitary science, medicine, and surgery in different degrees in different parts of India can only be completely understood by those who have been there, particularly by those who have practised medicine there Our regular letters from different Indian stations have, we believe, served to open the eyes of the British practitioner to the hardships of the situation which his colleague in India often occupies, while to the public these hardships have been made more or less familiar through the works of RUDYARD KIPLING, particularly in his collaborated novel "The Naulakha." Many will therefore appreciate the degree to which London, its health, and its hospitals may have impressed those oriental visitors whose sojourn among us has been lengthened by reason of the KING'S illness.

That illness has been the incident of the present year which has practically effaced all others and no doubt the part played by surgical science in the saving of the life of King EDWARD and the impossibility of developing surgical science without hospitals are the points which most readily rivet the attention of rulers of countries in which surgical science is a foreign import of recent date not always regarded with the fullest confidence. With us the presence of hospitals is a fact of our daily lives often forgotten in health by those who when sick or injured hasten to avail themselves of the aid offered To the Maharajah of JAIPUR, and also to the other distinguished visitors of high rank who came to London to assist at the Coronation we would point out that the treatment pursued in the case of King EDWARD would have been pursued equally effectually had His Majesty been a poor man who owing to his want of means had had to be conveyed to one of our great hospitals. Such considerations as these may well affect the mind of a benevolent ruler desirous to assist a science the developments of which are likely in an increasing degree to improve the lives of his own subjects. By Londoners the munificence of the Maharajah of JAIPUR will be accepted as useful practical assistance to the institutions of which they are justly proud and as a compliment to the monarch whose Coronation as King of Great Britain and Emperor of India has been for a brief period delayed while the full significance of a gift which emphasises the unity of India with the British Empire should be missed by none.

The Retirement of Lord Salisbury

THE present has been somewhat hastily regarded as an age of young men and it is true that here and there positions which our forefathers were wont to regard as the presumptive rights of seniority if not almost of senility are now taken by men in the prime of life But it is equally true that in many walks of life promotion now comes more slowly than it did to our grandparents. But this much is certain—in no age has there been seen to greater advantage than the present the combination of youthful attributes with advanced years. We might almost call the preservation of youth a special attribute of modern times and it is in this sense, rather than in the direct one of the advancement of men actually young that we may justly term the present a young man's age. It is a time in which old people remain still young to a degree that obtained less frequently formerly Her late Majesty Queen VICTORIA was a fine example of the way in which a trained exercised and well balanced mind can deride the encroachment of advancing years Mr GLADSTONE was in this respect perhaps a still more eminent instance, and Lord SALISBURY provides a third example An old man in years—for after the allotted span none may dispute the adjective old—Lord SALISBURY yet has an intellectual energy and keenness that many a younger man sighs for in vain. Forcible speech is a sign of youthful vigour and some of those short impressive sentences which often characterised the late Premier's remarks rank him still as among the young intellects of the day

But even those of the most vigorous mind are bound to feel the advance of years in some degree And deeply though all must regret the necessity for Lord SALISBURY'S retirement, yet it can be realised that possibly he has given in retiring one more proof of that sound judgment which makes his very retirement the more to be lamented Although he can bring to his political labours an energy equal to and an experience far surpassing that with which many younger men are endowed yet Lord SALISBURY no doubt feels now that his day is past for that resistless activity that easy adoption of a multitude of burdens which may be looked for in a younger man while he holds the position of Prime Minister Further the case is not the same as it would be were Lord SALISBURY'S successor a stranger or an opponent. Whatever objections may have been insinuated against the family nature of some Ministerial appointments at any rate at the present moment we must realise a great benefit in having in important positions men who will be able to avail themselves in necessity of Lord SALISBURY'S unrivalled experience. We need not doubt that his help will be forthcoming if wanted privately it may be, but in none the less an invaluable manner Assistance of this kind can be asked by and given to a near relative in a manner which would be awkward in the case of men less closely connected

To the medical profession Lord SALISBURY'S character as a man of science and a student has always rendered him a person of particular respect and admiration. More than the ordinary individual the medical man can sympathise with and admire, the attitude of mind of a man preeminently of affairs" who seeks diversion from his worldly business in thinking out the truths and penetrating the mysteries of scientific problems. Many a busy practitioner in his digressions into botany biology, or chemistry may have reflected sympathetically upon the recreations of the great Prime Minister himself an ardent practical student of the science of chemistry Moreover it is pretty certain that with this scientific mental bias Lord SALISBURY is little likely to have sympathised with, as he certainly did not support the indifference to medical questions which has on more than one occasion blotted the agenda of recent Parliamentary sittings. Mr. BALFOUR, we gladly and readily believe, is also disposed to regard with due seriousness any medical question that may be brought to the attention of the House of Commons. The influence of medical opinion upon that of the public has steadily increased in recent times together with the rise in the standard of medical education and with the enormous strides that medical and surgical knowledge has made. Medical men hold a position and medical matters have assumed an importance in the eyes of the nation at large that have never hitherto been reached. The interest in matters concerning our profession, and the confidence in its members which have been so manifestly displayed both by our late QUEEN and our present KING have done much to strengthen the public conviction of the importance and wide influence of medical affairs The time may still be far distant when this aspect of national affairs shall have the official representation which many believe it should carry We may have to wait a long time for a Governmental department or a Minister of Medicine, though such a development is far from being merely the wild dream of one prejudiced in favour of the medical profession. Nevertheless, even to-day no Government, no Prime Minister, can well afford to ignore the medical view of many questions of national importance, and we may congratulate ourselves that, if in losing Lord SALISBURY we miss a man by whom this aspect of things was never likely to be underrated, yet we have gained in Mr BALFOUR a Prime Minister who is sure to take the philosophic, the wisdom loving, view Mr BALFOUR is equally unlikely to under estimate the importance of the medical aspect of many political considerations

Tuberculosis in Asylums for the Insane.

THE question of tuberculosis in asylums for the insane has in the course of the last three years passed from the academical to the practical stage and may now be regarded as having reached a position of importance second only to the general problem of the prevention of mental disease. In an annotation which appeared in THE LANCET three years ago[1] attention was called to some of the more important points in relation to the causation and spread of phthisis in the insane and to the need for prevention. In November, 1899, at a general meeting of the Medico-Psychological Association held in London the question of the necessity for isolating the tuberculous insane was discussed and an important motion was passed unanimously to the effect that it should be referred to the Council of the Medico-Psychological Association to consider as to the appointment of a committee for the investigation and collection of evidence and for practical suggestions as to the isolation of tuberculous patients in asylums At a meeting held in May, 1900, a Tuberculosis Committee was duly appointed to carry into effect the above resolution. This committee succeeded in collecting important facts and evidence as to the prevalence of phthisis in asylums Returns on specially drawn up schedules in the form of question and answer were received from 111 public asylums in Great Britain and Ireland, and interim reports based on these were from time to time drawn up after careful consideration and discussion by the committee. The complete report in its final form has just been published and is a document full of important facts and weighty suggestions

The main conclusions reached by the committee are that phthisis is prevalent in our public asylums to an extent which calls for urgent preventive and remedial measures, and that a large proportion of patients contract phthisis after admission into the asylums The susceptibility to acquire the disease seems to be higher in patients drawn from the large towns of England and Wales, with their factories and slums, than in those belonging to the rural population Thus it is found that, whereas the average death-rate from phthisis in asylums with patients from a rural population was 16 per 1000, it was 30 per 1000 in asylums the inmates of which had been town dwellers, and 25 per 1000 for a mixed population. The committee points out that overcrowding and the consequent deficiency of air-space are the most important factors conducing to the high death rate from phthisis in asylums It is "satisfied that there is not sufficient cubic space per patient in the great majority of our large asylums," and adverts to the fact that where the inmates are made to spend as many hours as possible in the open air the death rate from phthisis is appreciably lowered. In the interests of uninfected patients it is recommended that overcrowding must be checked before we can hope to lessen the death rate from phthisis More especially does this apply to the sleeping accommodation of our large asylums where large numbers of patients are congregated in huge dormitories "We are of opinion," add the members of the committee, "that the predisposition to, and the actual infection of, phthisis is to a very large extent started in the sleeping rooms of our overcrowded asylums" The committee, after fully discussing the matter in its report, recommends that an air space of 1200 cubic feet with efficient ventilation should be the minimum provided for each sleeping patient, and a supplementary report upon the heating and ventilation of asylums is appended which deals with the subject in a very practical manner

To prevent the spread of infection by the sputa of patients it is recommended that all the wards and sick rooms should be provided with special vessels or spittoons containing disinfectants into which patients should be taught to expectorate, and that the bedding and bed-mattresses of every patient should be freely exposed to fresh air and sunlight daily It is urged that regard should be had to the dietary of patients, so that sufficient variety of food may be secured and that a sufficiency of fats may be present in the food, a point the importance of which was demonstrated by Sir JAMES CRICHTON BROWNE during his directorship of the West Riding Asylum 30 years ago The diagnosis of phthisis at an early stage is surrounded with especial difficulties in the insane The plan of weighing every suspected case weekly to ascertain loss of body weight, and the daily taking of temperature every four hours to detect elevations of temperature in the afternoon or evening, are important aids to diagnosis Tubercle bacilli cannot, as a rule, be recognised in the sputa in incipient cases of phthisis, but it is pointed out that the tuberculin test is a valuable one if carefully and judiciously employed, and that in conjunction with the indications afforded by the weights and temperatures of patients a diagnosis may be made in many early cases When signs of early phthisis are thus found it is imperative that isolation should be practised, this is strongly emphasised in the report. As a matter of fact, in a few asylums isolation has already been adopted, and honourable mention should be made in this connexion of the County Asylum at Lancaster, where Dr D McK. CASSIDY, the medical superintendent, has employed it for the past 12 years, with the result that since its adoption the tuberculous death-rate of the institution has decreased 50 per cent.

New asylums in course of erection, such as those for the counties of Warwick, Leicester, and Rutland, and for the district of Belfast, are being provided with isolation blocks and detached villas for the open air treatment of phthisical patients. The ideal isolation hospital should stand on sandy or gravelly soil protected from north and east winds and should not be of too great a size. The committee wisely recommends that the accommodation of such a sanatorium should be for not less than 50 or more than 200 patients Finally it is urged that where permanent buildings for isolation and open air treatment are not available in existing asylums temporary structures erected in suitable situations should be made use of or special wards and airing courts should be set aside for such purposes. The committee concludes that it is only in some such way as the above that the hope of lessening the high death rate from phthisis in asylums for the insane can be realised If the principles of isolation and open-air treatment be recognised as imperative the details are easy of solution and the carrying-out of them may be safely left in the hands of the medical superintendents and the committees of management.

---

[1] THE LANCET July 15th, 1899 p 167 "The Insane Population and Phthisis"

Annotations

"Ne quid nimis."

INSANITY AND THE DEATH PENALTY

WE have received some correspondence in addition to a letter which we published in our issue of June 28th[1] with regard to our leading article[2] dealing with the case of a man named Simmons, tried at Dorchester assizes for murder and acquitted on the ground of insanity We have little to add to what we then wrote. The case was one no doubt, upon the border line, and the defence which ultimately proved successful might have failed without any considerable surprise or comment being excited The question of the mental condition of the prisoner when the criminal act charged was committed if such a question be raised is one of fact for the jury to decide. Some criticism appears to have been evoked by the refusal of the learned judge who tried Simmons to allow medical evidence of his sanity to be given as part of the case for the prosecution and in anticipation of the evidence about to be given for the defence. The judge was strictly right according to law in refusing to receive this evidence at this point in the trial, although some judges we believe, have adopted a different course in similar circumstances. The accused person is assumed to be sane until the contrary has been shown, but if evidence of Simmons's sanity had been tendered later in rebuttal of the evidence of insanity given on behalf of the defence Mr Justice Bucknill would have had no choice but to accept it That such evidence, if there is any should be given as rebutting evidence seems to be clear from the procedure adopted in trying McNaughton to whose case we referred in our previous article (see 4 State Trials, New Series, at p. 924) but no rebutting evidence, we believe, was offered at the trial of Simmons. The administration of the criminal law neither is nor ever can be perfect. We aim at the dispensing of even-handed justice to all classes and degrees of wealth and poverty and as far as the integrity and zeal of our judges and the desires and ambitions of our advocates and officials are concerned we succeed. There is, however a personal element in such matters which becomes more conspicuous the more important the trial may be and cannot at any time be got rid of altogether In a murder case some judges feel more acutely than do others the responsibility for the life or the death of the accused person which undoubtedly rests upon them. Advocates are not of equal skill and experience. Prisoners are of different degrees, financially and socially as well as mentally Some have relatives able to afford the best possible legal advice and to bring the witnesses necessary to establish a defence, even those that at first sight seem hardly essential to the case set up, and willing to exert themselves to the utmost to secure an acquittal or to establish a defence such as that of insanity Other accused persons are poor, their relatives are tired of them or otherwise unwilling or unable to interfere, and although the Treasury will do anything reasonable to assist a prisoner in establishing his innocence it cannot be expected to help in raising a defence, such as that of unsoundness of mind unless those upon whose advice it relies are clearly of opinion that there is good reason for such a defence being raised. We are therefore left to draw the conclusion, quite apart from the particular case which we have been considering that some persons escape legal penalties which others of equal guilt or innocence but less favoured by circumstances undergo. It is not a satisfactory conclusion but if we take into consideration the human element that enters into crime and criminal trials we can arrive at no other and can only try to ensure that the element of chance, where it exists, shall be reduced to the smallest possible proportions. With regard to a letter which we printed last week from the solicitor entrusted with the defence of Simmons in the case tried at Dorchester we have no doubt of the accuracy of what he writes. It does not, however seem to us to affect in any way the conclusion to which we came in our leading article, which was that a murderer in whose case there has been an absence of self-control owing to mental infirmity may now escape the capital penalty which would have been meted out to him in days so recent as the middle of the last century We abstained from saying that his escape was in any way a matter of certainty and we cited the case of Simmons as an instance in which the law as laid down in McNaughton's case would hardly have excused the prisoner quoting with reference to his mental condition the evidence of Dr W B. Morton. Mr Malim does not correct us and we conclude that Dr Morton did not, in fact, go further than the expression of the view that at the time when Simmons committed the crime he had not a full appreciation of the nature and quality of the act. Absence of proof of motive where a murder has been committed in the circumstances described and the principal witness as to possible motive is consequently absent, should not form an important element among the considerations leading medical men to their conclusions as to the mental condition of the accused person.

THE SANITARY OATH IN BRITISH COLONIES

FROM a West Indian newspaper we learn that Dr R. C Bennett, a medical man practising at Trinidad, recently objected to kissing the Book as a preliminary to giving evidence in a murder trial. The judge informed him that he would like to see the law amended but that he was there to administer it as it stood and that unless the objection to the oath was on religious grounds affirmation was not permissible. Subsequently on Dr Bennett stating that he did not believe in certain portions of the contents of the Testament which he was asked to touch with his lips he was allowed to affirm. It will be remembered that in England there is no direct authority in any statute or rule of procedure for the kissing of a Testament by witnesses It is a practice of no great antiquity, the origin of which has, however, been forgotten, while the Oaths Act, 1888, permits any witness who chooses to do so, to take the oath in the Scotch fashion with uplifted hand, without any question being asked him as to his religious belief We commend this section of the Oaths Act to colonial legislative bodies The reasons which cause us to consider the kissing of a book that has been similarly treated by thousands of other persons of all ranks and degrees of cleanliness to be a nasty and possibly dangerous proceeding apply with no less force in hot climates and in the midst of populations neither cleaner nor more careful in their regard for the public health than are our own countrymen The section in question is as follows "If any person to whom an oath is administered desires to swear with uplifted hand in the form and manner in which an oath is usually administered in Scotland he shall be permitted so to do, and the oath shall be administered to him in such form and manner without further question" The oath in Scotland is usually administered by the presiding judge, both judge and witness standing, the latter raising his right hand and repeating after the former "I swear to Almighty God, as I shall answer to God at the great day of judgment, that I will speak the truth, the whole truth, and nothing but the truth" Few will be found to deny that this solemn formality, in addition to being more cleanly, is far more likely to bind the conscience of a witness of whatever nationality and colour than the perfunctory kissing of a Testament at the conclusion of a sentence repeated to, but not by, the person sworn

THE DESTRUCTOR NUISANCE AT TORQUAY

WE have more than once had to comment in these columns upon the nuisance that is caused to certain of the inhabitants of Torquay under adverse atmospheric conditions by the fumes from the chimney of the refuse destructor We have received the following letter from Messrs Goddard, Massey, and Warner, Limited, with reference to the comments which we have felt it our duty to make —

The Editor
THE LANCET
1 Bedford street Strand W C

DEAR SIR —Our attention has been called to comments you make upon the Torquay Refuse Destructor, which has a tendency of seriously interfering with our business We have noticed these comments for a considerable time but thought they would be abandoned and if we see anything further we shall be reluctantly obliged to take such steps which are necessary to protect ourselves against such observations

We are yours truly
GODDARD MASSEY AND WARNER, LIMITED (per H M)

Considering how very serious is the position taken up by the writer of the above letter we do not think that much care has been shown in the wording Messrs Goddard, Massey, and Warner complain, it will be seen, that the Torquay refuse destructor is interfering with their business The destructor is situated in Devonshire and their business premises are in Nottingham, so that the inference to be drawn from their words is that the smell from the refuse destructor is worse than we have ever suggested We must not, however, be betrayed into flippancy, for we feel that when Messrs Goddard, Massey, and Warner took upon themselves to write to us in such terms they did a thing which must not be met with laughter For nothing less than the suppression of what we believe to be the truth is demanded of us Presuming, then, that it is our comments and not the fumes from the refuse destructor which are interfering with Messrs Goddard, Massey, and Warner in their occupation as engineers we take this opportunity of informing the firm that what we have written has been written upon public grounds We have not the slightest bias against them or the slightest desire to damage their business, but while the nuisance which is caused by the Torquay refuse destructor continues we shall consider it our duty to continue to call attention to it. And this we must do, despite all threatening, in discharge of our duty to the community It is, by the way, the situation of the destructor with which we have found fault, a point which, although Messrs Goddard, Massey, and Warner have "noticed these comments for a considerable time," appears to have escaped their attention We are perfectly happy to publish in THE LANCET any criticism of our words that is demanded by accuracy The subject has been dealt with in detail and can be contradicted in detail if we have been betrayed into error while writing in the interests of public health But we cannot promise Messrs Goddard, Massey, and Warner, as a reply to their ominous communication, that we will publish no more comments upon the Torquay refuse destructor

A NEW TREATMENT OF HOOLIGANISM

THE prevalence of ruffianism in the London streets is complimentary neither to our modern civilisation nor to our existing legal methods Magistrates have but little power and do not always use such power as they have. Mr Horace Smith, however has introduced a new treatment which we earnestly hope will prove successful. On July 14th he had before him two young ruffians named Beake and Young These with others of like kidney made themselves unpleasant in Chelsea on Sunday night and when arrested some of the gang shouted, "Off with your belts, lads, and put them through them" Young was wearing a heavy belt studded with brass badges and with heavy buckles Mr Horace Smith addressed them as follows —

> Had there been any evidence that the threat made use of was acted upon and that one of these formidable-looking belts had been taken off to be used I would have sent you both for trial for a riot and seen what a judge could do to stop this scandalous state of things in the London streets My powers are not so large as I could wish, for what is the use of a 40s fine to stop this sort of ruffianism? You would laugh at such a punishment There is, however, another way of dealing with such cases I am going to exercise it now and in future. You will each of you find two sureties in £25 each to be of good behaviour for six months and in default you will be kept in prison for that period

Personally, we think that 50 lashes would be a much more binding security than £50 or six months' imprisonment. If Beake and Young had been taken straight from the dock and had been given a sound flogging in the presence of no one but a constable and the administering warder their zeal would soon cool Preventive measures for the young and budding hooligan should certainly be undertaken, but the full grown plant must be reasoned with by appealing to his sense of pain and that in circumstances in which there is no gallery to play to

PUBLIC HEALTH OF TRINIDAD AND TOBAGO

THE official report of the surgeon-general of the colony shows that during the year ended March 31st, 1902, there was no epidemic prevalence of disease in Trinidad and Tobago, but there was more than the usual amount of sickness, especially in Port of Spain, the capital of Trinidad, the cases being principally acute diarrhœal disorders, measles, whooping cough, chicken pox, and typhoid fever Malarial fever occurred as usual in all parts of the colony but was generally of the benign type, only one case of blackwater fever presented itself During the period in question 6097 children were successfully vaccinated, the proportion of vaccinations to births was about 70 per cent., the lymph seems to have been sent from England and complaint is made of its inferior quality for the greater part of the year The quarantine authority placed 57 vessels under quarantine observation, the aggregate of crews and passengers being 3883 and 2001 respectively The present surgeon general of the colony is Dr James A De Wolf who was in 1901 appointed to the vacancy created by the retirement of Sir Francis Lovell The appendices to his report give a variety of statistical and other information relative to the public medical institutions of the colony—namely the Colonial Hospital at Port of Spain the San Fernando Hospital, eight district hospitals three hospitals for yaws, the lunatic asylum the leper asylum and the house of refuge. The total admissions to these various institutions during the year ended March 31st, 1902, was 12,392, and there were 1681 deaths. At the hospital for yaws 88 cases remained under treatment on March 31st, 1901, and 736 cases were admitted during the ensuing 12 months—namely 500 at St. Augustin 140 at St Clair, and 96 at Arima. There were, therefore, 824 cases under treatment, of which Dr De Wolf says that 526 were cured 13 died from various intercurrent diseases, and 285 remained under treatment on March 31st, 1902. He is of opinion that the segregation and treatment of the disease in hospital have led to satisfactory results and that the heavy expense incurred in establishing and maintaining this system has been justified. With respect to treatment Dr J R. Dickson of the St. Clair Hospital mentions that it consists chiefly of the internal administration of iodides, principally iodides of iron or arsenic and iron, together with daily baths in which soft soap is liberally used, and the local application of antiseptics such as carbolic acid lotion, zinc sulphate or copper sulphate, and an ointment or oil of iodoform carbolic acid, or mercury When the tubercles were large and exuberant the most prominent were from time to time excised. Dr F A. de Verteuil of the Arima Hospital has found treatment by thyroid extract to be of the utmost value, especially when the *eruption was tubercular* and a combination of salicylic acid and collodion proved itself a good local application to the hard crust-covered tubercles. Both these gentlemen agree that daily baths and a liberal diet are of the first importance in the *treatment of yaws* *The maximum* and minimum shade temperatures during the year were respectively 94·0° F in April 1901, and 61·0° in December 1901, and also in January 1902. The total rainfall for 12 months was 55·78 inches, The census of 1901 *showed that* the population of the colony was 273 899

THE HINDRANCE TO PROGRESS CAUSED BY THE EXPENSES OF TRANSPORT

IT is well nigh an axiom that England discovers but that other nations profit by the discovery In the race for industrial supremacy it is evident that the English nation must soon lag behind *if it does not bestir itself. Its* opportunities, which are not less favourable than those possessed by other countries, are not seized owing to a failure to realise their immense bearing on industrial success. One great aim of this country should be to acquire a *means of* transport which would cheapen the carriage of goods from one part of the country to another It is well known that it is cheaper to import many goods from abroad into England including articles of food, than to send them to London from the country districts near at hand Brittany butter is a good deal less expensive than English butter on account of the cheapness with which it can be transported. English railway rates have done more than anything else to cripple the resources of the land and yet transport abroad is sufficiently cheap to make growing to be profitable both for consumption in the country and for consumption out of the country as well. Surely this is an *anomalous and reproachable* state of things. Still we do not believe that the anomaly and the reproach cannot be removed England is a long way ahead of many other countries in regard to canal ways. We possess, indeed over 4000 miles of artificial waterways. But the method of working them is archaic and utterly out of keeping with the clear indications of modern progress The canal waterways of England it is true, are not idle, but they might as well be so considering the extremely unscientific way in which they are worked. It is hardly possible to estimate the extent of the influence upon our industrial position which the improved working of our waterways would have if transport could in this way be made reasonably rapid and cheap. And there is no reason why such a fillip to this method of transport should not be given. If railway companies pretend that they cannot cheapen rates some other method of transport must be found. In Germany and Holland transit both by railway and water is infinitely cheaper than it is in England Why is it so? Surely we might have a useful commission of inquiry upon this subject, which however we may anticipate would find as an answer apathy, mere apathy We are glad to see that this and cognate subjects have recently been discussed at the Liverpool meeting of the Society of Chemical Industry the discussion being opened by a paper by the President, Mr Livinstein who chose for its title, Education and Legislation their Influence on Trade and Industry "

THE NATIONAL SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN

THE latest annual report of the National Society for the Prevention of Cruelty to Children which is *published in this* month's issue of the society's journal, contains a highly satisfactory record of progress The total receipts for the year which has just closed amount to £73,875, and this sum does not include the funds collected by the Scottish branches which are under a separate administration. In England Wales, Scotland and Ireland there are now 934 centres of work New and commodious offices have been opened in Leicester square, London a large part of the cost incurred in this undertaking being met by colossal contributions from two friends of the society, Mr Astor and Mr Woolcott Thompson respectively These statements are in themselves remarkable Their effect is very greatly enhanced when we compare the present position of the society with that which it occupied at the date of its first report 13 years ago Omitting Scotland for the reason above given we find that there were then 52 working centres and the income reached a total of £8871. The number of cases under supervision was then 3947 Last year (over an immensely extended area) it was 32,767 When we remember that the object of the society is primarily that of *reformation, that it is teaching* reckless people to live reasonably and humanely with their own kind, and that its efforts towards this object are coming to be understood and approved even by the very people who might be expected to oppose them, we desire no further *proof that it is working* on the right lines and deserves all the prosperity which may come to it.

ACROMEGALY AND MYXŒDEMA IN THE MIDDLE AGES

ACROMEGALY and myxœdema are said to have been first described the one by Marie and the other by Gull in 1886 and 1873 respectively But the type of figure and *feature* produced by these two diseases must have been recognised as something markedly peculiar for many centuries. To go back no later than the eighteenth century every medical man must have been struck by the acromegalic type of many of Rowlandson's characters a fact which we have remarked upon in THE LANCET But we have recently come across a far earlier example which is so forcible in many ways that we think it worthy of note in our columns There is at present on *view in a little gallery in Ryder street, St. James's, S W* belonging to Messrs Carfax and Co an extraordinarily fine painting by Piero di Cosimo Many of our readers may know the Death of Procris" by this master in the National

Gallery, but the picture in the Carfax Gallery shows him in a very different light. The subject is the conflict between the Centaurs and the Lapithæ which took place at the wedding feast of Peirithous and Hippodame—a description of which is given by Ovid in the "Metamorphoses" According to the poet the bride was remarkable for her beauty—a quality not apparent in her picture But it is to the other Lapithæ represented in the picture that we wish to draw attention. Almost all of them, together with some of the Centaurs, have the typical facies of acromegaly, while the Lapith woman who is being carried off by a Centaur—she is standing on his back and is supported by a scarf round her neck—has in addition the pendulous belly of myxœdema Considering the date of the painting *circa* 1482, the anatomical drawing is wonderful. More especially is this marked in the strenuous figures of Theseus and Peirithous and in the masterly way in which the foreshortening of the various fallen bodies is managed. It is true that a dead Lapith lying near the centre and upper part of the panel is singularly badly drawn, but the representation of one of the fallen Centaurs in the foreground is surprisingly learned To return, however, to medicine, to us the internal evidence seems convincing that Piero di Cosimo was familiar with the facies of acromegaly and must have been struck with its fitness to express a certain brutishness of type It is more likely that he had seen the type than that he should have accurately evolved it out of his inner consciousness

THE DISTRIBUTION OF PLAGUE

THE weekly return of the Director General of the Sanitary Department of Egypt shows that for the week ending July 6th there were 9 new cases admitted, 2 of which occurred in Europeans The deaths numbered 7, the recoveries 4, and 8 cases remained under treatment With respect to sanitary measures 13,378 rooms were disinfected and 1581 were limewashed, 99 sacks of effects were disinfected and 1141 sacks of rubbish were burned The number of rats killed by burning was 1009 One of the fatal cases of plague occurred in a Greek at Port Said, where no cases have occurred since Sept. 26th, 1901. The Director General, however, says that "all the necessary measures having been immediately taken I am entitled to hope that the disease will not assume a large proportion" A telegram from the officer administering the Government of Hong Kong (received at the Colonial Office on July 15th) states that for the week ending July 12th there were 28 cases of plague and 27 deaths from the disease.

CLAYTON GAS

SOME remarkable experiments have demonstrated the superiority of Clayton gas to pure sulphurous or carbonic acid gas for the purpose of destroying rats as a prophylactic measure against plague. The practical results obtained under the supervision of Dr Edward Walford at Cardiff are described in our "Public Health and Poor-law" columns this week (p 178) The gas is essentially sulphur dioxide, but there occurs in it by the particular method by which it is obtained what may be called an impurity, without which, however, the effect upon rats would not be so disastrous. This impurity is sulphur trioxide, the presence of which is manifest from the fuming properties of the gas Clayton gas is produced by the combustion of sulphur in a current of air during which the temperature rises sufficiently high to lead to the formation of some amount of sulphur trioxide. The apparatus is handy and convenient and free from any element of danger and has been tried on a very large scale and in every instance the effects on rats have been most destructive and vastly superior to those obtained with pure sulphur dioxide. The gas is used mixed with air in the proportion of 10 to 15 per cent. It is stated that less than 5 per cent. of the Clayton gas will destroy rats and other vermin, while at least 15 per cent of pure sulphur dioxide is required for the destruction of vermin life Odd as it may appear, Clayton gas has no appreciable action on coloured materials, foodstuffs, paints, or dry metals except in a moist atmosphere The fire-extinguishing properties of Clayton gas are also remarkable, a mixture containing 8 per cent rapidly extinguishing burning materials. For the purpose of disinfecting ship holds or for destroying vermin the fact that this gas puts out fire gives it a double advantage. The apparatus is thus available for either disinfecting purposes or for the extinction of fire as the case may be. The method was devised by Mr T A. Clayton of the Clayton Fire Extinguishing and Ventilating Company of 22, Craven street, London, W C

FIVE INSTANCES OF GENERAL PARALYSIS IN BOTH HUSBAND AND WIFE

IN the *Archives de Neurologie* for June last Dr P Keraval, medical superintendent, and Dr G Raviart, assistant physician, of the asylum at Armentières, record five instances of general paralysis in married couples, husband and wife being equally affected with the disease Syphilis was not present in every case, probably because it is not, say Dr Keraval and Dr Raviart, the sole or exclusive cause of general paralysis The following is a brief epitome of the five cases The first case was that of a man, aged 41 years, without hereditary predisposition to insanity He contracted syphilis while serving with his regiment He was married but had no children The symptoms of general paralysis began 15 years after infection His wife was a healthy woman of temperate habits The symptoms of general paralysis appeared in her case shortly after the death of her husband in 1896, but for some time prior to that she had symptoms indicative of tabes The second case was that of a man, aged 50 years, free from syphilis or from any hereditary taint of insanity His married life was unhappy as his wife deceived him and finally left him to abandon herself to a loose life He grew depressed thereafter and within 15 years developed general paralysis The wife who abandoned him to lead a life of prostitution became a general paralytic, but it could not be positively ascertained whether she had become infected with syphilis Her habits were, however, for years markedly intemperate before general paralysis appeared The third case was that of a man, aged 48 years, a waiter by occupation. There was a hereditary tendency to gross brain disease Shortly after marriage he developed melancholia with suicidal ideas He then passed through a state of mental enfeeblement and lapsed rapidly afterwards into general paralysis His wife, aged 49 years, was addicted to alcohol but had no hereditary taint of insanity She developed melancholia and passed through a stage of depressive delusions into general paralysis The disease was rapidly fatal in this case in both husband and wife. In the next case the man was aged 38 years and presented no traces of syphilis He had an accident to the head in March, 1889, which made him ill and caused him to suffer from terrifying hallucinations of wild beasts and the like He got rapidly worse and he was placed in an asylum. He subsequently developed symptoms of general paralysis and the disease ended fatally in March, 1897 His wife seemed a woman of good health, free from alcoholism and syphilis. After her husband was placed in the asylum she lost a daughter and suffered much from grief and destitution. In July, 1894, she developed delusions of grandeur and other symptoms of general paralysis and died four years later from the disease. The fifth and last case was that of a man, age

47 years, who presented no evidence of syphilis and was of temperate habits A twin brother developed general paralysis at the age of 39 years consequent upon worries and grief. The patient was married and was the father of five children He developed symptoms of general paralysis at about the age of 44 years and died after having been in an asylum for two years and six months. His wife was a woman of temperate habits and free from hereditary predisposition to insanity In her case the only cause that could be found to account for her illness was grief and anxiety at her husband s illness and at his being placed in an asylum. Two years after her husband s sequestration she developed distinct signs of general paralysis. The disease ran a very rapid course and proved speedily fatal. The observations made and recorded by Dr Keraval and Dr Raviart are by no means exhaustive and complete but lend support to the view that, apart from syphilis other factors, such as alcoholism grief and destitution, head injuries and an obscure bodily predisposition to the disease not as yet well understood, lie at the roots of the causation of general paralysis of the insane.

THE APPOINTMENT OF MEDICAL OFFICERS TO WORKHOUSES AND OTHER INSTITUTIONS

The Rev George A. Seymour has sent us a letter with the above heading in which he makes some judicious observations on the unreasonableness of the system according to which the salaries of Poor law medical officers may be made inclusive of the cost of the medicines and surgical appliances required by the patients. The letter is too long for publication in full, but its general tenor will be apparent from the following extracts.

> I would observe upon the subject of the appointment of medical officers to workhouses and various benevolent institutions that it has become a very frequent practice to unite under one head of payment the stipends of such officers with the supplies of medicines and perhaps also of some appliances required by sick persons, this method being adopted under the plea of avoiding trouble and of saving expense. But with no certain knowledge beforehand of the amount or nature of the sicknesses to be dealt with in any given time, how can justice be done either to the medical officer or to his patients under these circumstances, and how can the use of the expensive medicines required in some cases be expected? Does any intelligent person having cattle in his fields, or any trainer having valuable horses in his stables, enter into terms with the veterinary surgeon to deal with cattle or horses after this manner? No sensible person would venture on such a scheme. These arrangements are made under the plea of saving expense, an intention justifiable enough when the case is equitable and right, but in economics it is a grave question whether wrong and unjust methods are in the long run really more profitable, that is, more saving in a money point of view than just ones ”

A CASE OF AORTIC ANEURYSM SUCCESSFULLY TREATED BY THREE HYPODERMIC INJECTIONS OF GELATINISED SERUM

In the *Archives de Médecine et de Pharmacie Militaires* for June Surgeon Major Dusolier reports a case of aneurysm of the abdominal aorta which was successfully treated by the subcutaneous injection of gelatinised serum according to the method recommended by Dr Lancereaux. On the morning of Sept. 7th 150 grammes of artificial serum containing 1 5 grammes of gelatin were injected into the left flank. There was no local reaction but in the afternoon the patient s temperature rose to 38° C. and his pulse increased from 85 to 95. There was also slight retention of urine The following morning these symptoms had gone and two days after the injection the patient, who till then had been greatly depressed, declared that he felt very much better The severe pain was considerably diminished and he could now remain in a sitting posture as long as he liked without being shaken by electrical discharges in his legs. ’ There was however, no improvement as regards the tumour Its volume remained the same and the throbbing vibration and systolic murmur were unaltered. On the 14th 200 grammes of artificial serum containing three grammes of gelatin were injected into the right thigh. Towards midday the patient experienced a violent rigor, his temperature in the space of two hours rose to 39° C and his pulse to 98. On the next morning not only was the general condition improved but there was also distinct amelioration in the local signs. Two days after the second injection the tumour had palpably shrunk its expansive force was much less and the space over which the murmur was audible had considerably diminished. On the 23rd 200 grammes of serum containing two grammes of gelatin were injected into the right flank. That evening the temperature reached 40° C while the following morning it was still 38° C The patient's pains had entirely vanished, he no longer suffered from lumbago, headache or vertigo. The troublesome feeling of anal protrusion of which he used to complain had also disappeared as well as the sensation of pricking and tingling in his lower extremities. On Oct. 4th he was discharged practically well. In conclusion Surgeon Major Dusolier draws attention to the febrile reaction which increased in severity after each injection. These operations were performed with strict antiseptic precautions and no local complication of any kind supervened. He regards the rising temperature as the index of the curative action of the gelatin and is also of opinion that the aneurysm was sacciform with a very narrow neck, thus lending itself to an exceptionally rapid cure.

HIGH FREQUENCY CURRENTS IN THE TREATMENT OF MALIGNANT DISEASE

In the July number of the *West London Medical Journal* Dr James Allan publishes an account of four cases of malignant disease in which great relief was obtained by the application of electric currents of high frequency and potential. The first patient was a female aged 48 years who was operated upon in July 1699 for sarcoma of the antrum invading the nasal cavity There was a recurrence in August, 1900 and some further growth was removed under cocaine. In July 1901 there was a fresh recurrence with much dragging pain which prevented her from sleeping and she was advised that a further very serious operation was necessary The growth was easily seen in the nasal passages. Dr Allan applied the current by means of a small condensor electrode passed into the nostril for 15 minutes each sitting using a primary energy of five ampères After the second application the pain began to subside and the growth to become less. In all the patient had 15 sittings, at the end of which the visible growth had disappeared and the pain was entirely gone, she returned to her home in the country and has since had no recurrence. The growth was a spindle-celled sarcoma. The second patient was a woman aged 37 years whose breast was removed for carcinoma in November, 1901 the axilla being cleared out very freely and a very bad prognosis being given. Three weeks after the operation Dr Allan commenced the high frequency treatment locally by the unipolar method using a primary energy of five ampères. The patient s weight was then nine stones and nine pounds. Her appetite speedily returned and she felt much better At the present time four months after the operation, she is in excellent health, her weight is 10 stones and one pound, and there is no sign of recurrence. She has had 30 applications of 10 minutes each sitting The third patient was a woman aged 63 years whose left breast was excised for scirrhus in August 1901. Two months after the operation signs of recurrence began. In the first week of November Dr Allan commenced the unipolar treatment locally for 15 minutes each sitting, using a primary energy of three and a half ampères After the fourth application the pain began to subside and the indurated parts to soften The patient's general condition improved rapidly, sleep returned, and her appetite became good. After 28 applications all trace of the recurrence had disappeared. The fourth patient was a woman suffering from epithelioma of the cervix too far advanced for operation. The case being a desperate one Dr Allan pushed the treatment much further than he had ever done before, and gave from 40 to 60 minutes treatment daily, using a primary energy of five and a half ampères A unipolar or condensor electrode was passed into the vagina and made to impinge against the growth The treatment was continued daily up to Jan 2nd, 1902, when the patient became very ill and it was not resumed till Jan 26th At present the growth seems to be entirely arrested and the patient feels very comfortable. Dr Allan uses an induction coil giving a 12 inch spark, with a mercury jet interrupter, working from the house main at a pressure of 210 volts with a D'Arsonval-Oudin high frequency apparatus

COLOUR AND COLOURING MATTERS

THE popular conception of the nature of colour is somewhat curious Perkin's discovery of the preparation of aniline dyes from coal tar (the first one, mauveine, was obtained in this way in 1856) is very generally attributed to his observation of the play of colours seen on the surface of a river into which tarry matters had been discharged Gasworks at one time were a common source of such a discharge. Colour, of course, is not an entity—it is an effect, like the rainbow, or shadow, or light itself The colour effects seen when any substance of an oily nature floats on water are due to the formation of a thin film following the natural spreading action of the oil on the water A thin soap film gives colours in the same way The fine play of colour is produced by the mutual interference of the light reflected from the two surfaces of the thin film. White light by undergoing a series of reflections and refractions, as through a prism, is split up into its colour components in accordance with the degree of refrangibility of each elemental colour The colours thus seen are not due to any specific substance which, like a green leaf, is endowed with the power of the selective absorption of light. The film is an analyser of white light, laying bare all its primary colours, a leaf is green or a flower red because of selective absorption The particular colouring matters known as dyes are, however, not only eminently endowed with the power of selective absorption in regard to light—a power which causes them to appear coloured—but their particles or atoms possess a strong faculty for wandering into fibres and fabrics, and moreover, of becoming dissolved therein. This wandering power and solubility in solid materials, possessed to such a high degree by dyes, distinguish them sharply from ordinary coloured substances In the former case the particles travel into fibre and are actually soluble in it, in the latter case, although penetration proceeds the actual solution of the colour in the material is not effected In short, a dyed fabric is nothing more than a solid solution of the dye stuff in the substance of a fibre Clearly Perkin's discovery had nothing to do with the pretty light phenomena of films. The number of artificial colouring matters prepared since that discovery, now nearly 50 years ago, has been enormous. It is estimated that at the present day over 3 000,000 different individual dye stuffs are easily accessible to our industries, while at least 25,000 form the subject of patent specifications The number of colouring matters furnished by natural agencies is comparatively small and those that do exist threaten soon to be ignored in favour of coal tar derivatives Perkin's great discovery has led to a complete revolution of the colour output of the world and has placed at our disposal an infinite series of colours of every variety and shade Moreover, it is interesting to remember that the aniline dyes have proved of great service in determining the nature of disease The germ theory of disease could not have developed so rapidly and on such definite lines as it has done had not aniline stains been discovered which were soon found to possess the power of marking and individualising the specific organism by dissolving in it and thus enabling in several instances an exact bacteriological diagnosis to be made

THE NEW MEDICAL STAFF COLLEGE

AS our readers are aware, the establishment of an army medical school or institution in this metropolis was a point on which we laid much stress in the series of articles which appeared in THE LANCET in connexion with the proposed army medical reorganisation, and it was one of the measures recommended by the War Office committee over which the War Minister presided This was in due time, followed by the announcement that the next session of the Army Medical School will be held in London But we have not yet had any official announcement as to what is about to be done to give effect to it or as to what is to become of the present school at Netley, with its teaching equipment and its professional staff The establishment of a medical staff college in London, if properly organised and carried out, will, for the reasons we have already given, be a great step in advance and will bring about important and progressive changes in the direction of developing the position and efficiency of the army medical service as a whole, but it will, we fear, be a somewhat costly undertaking In view of the competitive examination held this month, for which, we are glad to hear, the number of candidates is large, there is not too much time at the disposal of the War Office authorities to make their arrangements

CALEDONIAN MEDICAL SOCIETY

WE have already mentioned[1] the awards of the Gunning prizes of the Caledonian Medical Society The first prize of £20 was gained by Dr H. Cameron Gillies of London for an annotated reproduction and translation of a Gaelic medical MS in the British Museum, while the second prize of £10 was gained by Mrs K. Whyte Grant of New Zealand for an essay on the Influence of Scenery and Climate on the Music and Poetry of the Highlands Mrs Grant's essay is published in the July number of the *Caledonian Medical Journal*, of which it occupies rather over 40 pages Incidentally referring to the Ossianic poems she maintains that they are authentic productions of antiquity and quotes similarities between passages in them and in the East Indian Mahabharata and Ramayana. In conclusion she gives a long account of the myth of Cailleach Bheur which is interwoven with the folklore of several nations Mr Donald Mackinnon, professor of Celtic literature in the University of Edinburgh, contributes a genealogy of the medical family of the Macbeths or Beatons of Islay and Mull, together with a bibliographical account and two photographs of a Gaelic medical MS in the University of Edinburgh Under the heading of Medical Notes from Berlin Dr Donald Bremner Waters supplies some miscellaneous information which may be found useful by persons visiting Berlin with a view to medical study In the advertising pages of the *Journal* it is announced that by the kindness of Dr Stewart of Bacup the society is enabled to offer a prize of £10 for an essay on Old Highland Therapy The essays are to be written in English, are not to exceed 20,000 words, and are to be sent by May 1st, 1903, to Dr S Rutherford Macphail Rowditch Derby The twenty second annual meeting of the society will be held during the present summer—namely on August 15th—at Inverness

---

[1] THE LANCET Feb 15th (p 465) and June 7th (p 1618) 1902.

THE PREVALENCE OF SMALL-POX

THE following figures show the number of patients admitted to the various hospitals of the Metropolitan Asylums Board for the dates mentioned on Saturday July 12th there were 3 fresh cases on Sunday the 13th, there were 2 fresh cases on Monday the 14th there were 11 fresh cases, on Tuesday the 15th there were 4 fresh cases and on Wednesday the 16th there were 11 fresh cases.

PROPOSED JOURNAL FOR THE ARMY MEDICAL SERVICES

THE Director General of the Army Medical Service has issued a circular regarding the proposed establishment of a journal for the Army Medical Services. Sir William Taylor believes that a journal devoted to matters of professional and scientific interest would confer many advantages and be generally welcomed by army medical officers. Such publications are issued by the medical services of Continental Powers It is hoped that a journal conducted upon such lines as are set forth in the circular in question would not only enable medical officers to keep in touch with what is going on in the British service but with the advances and changes that are taking place in other armies The proposed journal would to a great extent take the place of the present appendices of the Army Medical Department Reports, but would contain, in addition to original articles of a medical surgical and scientific nature bearing upon army hygiene, reprints and translations from military medical, and other journals. In these and other respects such a publication would serve to draw out much information now latent and to focus a large amount and variety of useful and interesting knowledge which is now comparatively lost or rendered unavailable from being dispersed in so many different directions The Director General is naturally desirous of eliciting the views of his department on the subject and of ascertaining the amount of support which the proposal would be likely to meet with

ADMINISTRATION OF HIGHLY VOLATILE ANÆSTHETICS

WE noted in a recent issue an apparatus used in France for the exhibition of the more volatile anæsthetics such as chloride of ethyl It is stated that the apparatus in question hermetically seals the mouth and nose." That chloride of ethyl and some of its congeners and mixtures must be given by some apparatus which enables the administrator to minimise the access of air is obvious owing to their great volatility but we think that it is open to grave question whether the danger of their use is not accentuated when the patient is permitted to breathe only such air as is contained in his lungs at the time of the administration. It is patent that the requirements of the normal man are, as regards oxygen more than met by ordinary respiration and that even a temporary exclusion of atmospheric air may safely be permitted The danger lies in the fact that not only are many people unable to forego their supply of oxygen for any period without peril but that the struggling which not uncommonly is associated with complete exclusion of air is in itself liable to produce syncope. The tide of fashion, which exists in anæsthetics as in other sublunary matters is at present setting in favour of chloride of ethyl under various disguises and there is only too great a liability to forget that such volatile bodies are depressants and that their capacity for danger culminates when the mouth and nose are 'hermetically sealed "

MEDICAL EXCURSIONS TO GERMAN WATERING-PLACES AND HEALTH RESORTS

WE understand that the committee which organises medical excursions to German watering places and health resorts has arranged an extensive and varied programme. The number of the party is limited to 400 and it is stated that a great many names have been already received, so that early application on the part of those intending to join the excursion is advisable. Every information may be obtained from the secretaries, Dr W H Gilbert, Baden Baden and Dr P Meissner 81 Kurfürstenstrasse, Berlin The amount of the subscription is 150 marks (£7 10s.)

THE NAVAL MEDICAL SERVICE

THE communication from the Warden of the London Hospital Medical College which appeared under the above heading in the *Times* of Monday last, July 14th is worth the attention of our readers The letter has already been published in our columns[1] and commented upon, but our remarks will bear repetition The Warden very wisely and pertinently recommends that a naval surgeon should be allowed to hold a house surgeoncy for six months at his hospital after and not before, entering the naval medical service whilst counting his time and pay during the time he holds that post. By so doing the loss of time and seniority entailed by his taking up the appointment of house surgeon to a civil hospital before entering the naval service would be overcome. This as matters stand at present, deters medical candidates for the navy from seeking such posts. We have already expressed our concurrence in this view and we may add that we likewise concur in the other proposals contained in the Warden's letter If his suggestions were adopted we think that they would prove valuable and a considerable number of very desirable candidates who are now lost to the service would be secured

THE CEREBRO-SPINAL FLUID

THE nature of the cerebro-spinal fluid has recently been the subject of investigation by Professor E Cavazzani of the University of Ferrara, who gives his results in the first fasciculus for 1902 of the Archives Italiennes de Biologie." First, in regard to its alkalinity which he determined by lacmoid," he finds that in the dog the mean is 0 093 per cent. of NaOH and in the ox 0 104 per cent. the fluid being obtained from animals killed by bleeding In other cases the fluid was obtained during life by aspiration through the atlanto-occipital ligament. In dogs that were curarised the mean was 0 089 NaOH per cent. and in two normal rabbits it was 0 099 and 0 085 per cent. The importance of these numbers consists in the evidence which they afford that the cerebro-spinal fluid is not a mere filtration of the plasma of the blood, since it presents less than half the alkalinity of the blood In the next place the effects of various reactions such as tincture of guaiacum hydrochinone, gallic and pyrogallic acids, peroxide of hydrogen, and ortho-toluidine have led him to the conclusion that the cerebro-spinal fluid contains a ferment to which he has given the name of cerebro-spinase. This ferment possesses the power of destroying the reducing agent which is normally present in the cerebro-spinal fluid and is capable of oxidising glycose Professor Cavazzani adduces reasons for supporting the views of Knoll attributing variations of pressure in the cerebro-spinal fluid to venous influence At the beginning of asphyxia there is a diminution but subsequently an increase of pressure in the fluid and if the central stump of the vago sympathetic nerve is stimulated in the dog the fluid ceases to flow through a fistula. The results of his experiments have convinced Professor Cavazzani that the cerebro spinal fluid is a true secretion and is not lymph in the ordinary sense of the word As additional evidence in favour of this view Professor Cavazzani has studied the action of the substances termed "lymphagogues" by Heidenhain—namely, peptone and the extract of the heads of leeches, glycose, and chloride and iodide of sodium In no instance was there any acceleration in the flow of the cerebro-spinal fluid from fistulous openings

[1] THE LANCET May 3rd 1902, p 1221

WE have been informed that the Law Fund, the subscriptions to which have been regularly announced in our columns for the last few weeks, will be closed at the end of the month. Any of our readers who propose to subscribe should, therefore, not delay any longer, while we may remind them that a few more subscriptions will now make the fund a complete success.

Mr Alexander G R. Foulerton, director of the Cancer Research Laboratories, the Middlesex Hospital, London, W, has been appointed a member of the German Cancer Investigation Committee, the Comité für Krebsforschung

Sir A. Conan Doyle, M D, has been appointed Deputy Lieutenant of the county of Surrey

THE ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS FOR THE YEAR 1901

PART I REPORTS

FIRST NOTICE.

THE annual report of Dr Arthur Whitelegge, the chief inspector of factories and workshops, is published in the form of a blue-book of 292 pages Statistical tables are to be issued separately and a few necessary figures only are included in the volume which is now issued.

The present book contains a general report upon the work of the Factory Department during the year 1901 and a valuable summary written by Dr Whitelegge (pp iii.-xix) This is followed by the sectional reports of the superintending inspectors of the five districts into which the country is divided (pp 1-150), the reports of the principal lady inspector (pp 150-192), and those of the examiner of textile particulars (pp 192-194), of the inspector of cotton cloth factories (pp 194-204), of the engineering adviser (pp 204-206), and of the medical inspector (pp 206-245) The annual report for 1900[1] contained an interesting series of special reports which appeared in the form of appendices. The present blue-book contains two special reports, the first a very interesting one on the fencing of machinery as seen at the Paris Exhibition of 1900 and the second on accidents in docks. The remainder of the volume is occupied by a reprint of the statutory orders concerning factories and workshops which were made during the year 1901 (one of which was issued in regard to home work and the other in regard to birth certificates), a summary of the appeal cases in which the Board of Trade was interested (pp. 272-284), the special rules (established after Arbitration 1901) which are to be in force in the manufacture of earthenware and china, the amended special rules in force in trades in which the handling of hides and skins form a part, and finally the circular letter addressed to occupiers of factories and workshops in which such operations are carried on. The table of contents comprises one page only and, as in the case of the last report, there is no index. This omission, as we have had occasion to point out before, very seriously lessens the value of the report as a work of reference and causes a great waste of time to anyone who wishes to investigate any one particular subject, for such information may be found scattered through the various reports. For example, it may be necessary to look through the reports of each of the five superintending inspectors in order to be sure that no piece of information is missed It is to be hoped that an index will be published with Part II of the report, but it would have been much better had it been included in the present volume

At the end of the year 1901 the number of registered factories was 97,845, as compared with 95,664 in the previous year, and the number of workshops was 143 095 as compared with 137,648 Laundries are included in these estimates, but men's workshops, docks and warehouses are excluded The amount of work which is done by the department may to some extent be appreciated when it is said that during the year it had to deal with no less than 322,000 statutory reports from occupiers of premises affected by the Factory Acts Of these reports, 83,760 had relation to accidents, 936 to poisoning contracted in either a factory or a workshop, and 167,000—a large proportion of the whole number it will be observed—had relation to overtime

The monthly summary of reported accidents is now published weekly in the *Labour Gazette* and in regard to the statistical part it may be sufficient here to give a table comparing the number of accidents reported in the years 1900 and 1901 During the year 1901 there was some improvement in the methods of "fencing" used for the protection of those who work near dangerous machinery, but it was found in many cases that the workmen either rejected or misused the guards which were provided to ensure their safety from injury Employers, it was found as a rule, were willing to carry out the instructions given to them, but it frequently happened that in the case of newly introduced machinery which had obvious dangers nothing was done to guard the workers until the attention of the manufacturers was called to the peril by the inspectors The very valuable report by Mr C R. Pendock on the machinery exhibited at the Paris Exhibition incidentally gives some curious information bearing on this subject It appears that in the case of newly invented machinery the English manufacturers as a rule do not provide efficient fencing as part of the machine. It is not until the dangers are pointed out that the necessary protective fencing is provided In this respect some of the new German and French machinery forms a marked contrast to that of England and the report rather leads to the inference that some at least of the foreign makers rather unnecessarily emphasise the importance of the protective guards which they supply with their new invention. The general fact, however, remains that in the case of newly-introduced English machinery fencing is usually unduly neglected and in the case of similar foreign products such fencing is usually provided although, it may be added, it is by no means always particularly effective for the purpose which it is designed to effect. In one district (Blackburn) an accident insurance company has been of service in forcing on manufacturers the use of efficient protection for the operatives The Employers' Liability Assurance Company requires that those who take out its policies shall fence all dangerous machines.

Accidents in docks continue to cause much loss of life. Shipbuilding is, apparently of necessity, a dangerous trade. An experienced inspector at Newcastle gives it as his opinion that operations in ship construction are, and he fears always must be, more or less of a hazardous character Serious risk is run in rigging staging at great heights. Moreover, there is danger in working on the raised stages, for they are rarely fixed and they have no protecting rail. These platforms are often as much as 40 feet above the ground and the planks of which they are formed are loose. In some cases, also, a series of such stages is erected at different levels, so that the workers have a double risk—they may either fall off their perches or they may be struck by things falling down upon them from above Many of the accidents are due to the fault of the workers themselves and it appears that five out of a total of 22 fatal cases which occurred at Newcastle in the year 1901 in connexion with the actual building of ships were due to "carelessness on the part of the other operatives, such as the careless handling or throwing of materials and tools, removal of fastenings, &c." As a rule the men themselves fix the staging on which they work and it seems that in many cases they do not adopt ordinary precautions to ensure the efficient stability of the supports on which their lives depend In the opinion of Mr Low of Newcastle this criminal laxity is due to the laziness or to the meanness of the men. "I am afraid," he writes, ' the question is merely one of so many minutes lost in unproductive work "

---

[1] THE LANCET Sept. 28th (p 868) and Oct. 12th (p 998) and 26th (p 1145), 1901

The report of Mr A. G H Thatcher on accidents in building operations and of the means which should be adopted for their prevention appeared in the annual report for the year 1900 We were able to speak of Mr Thatcher's work[1] in terms of unqualified praise and we recommended that a copy of his report with its illustrations should be in the hands of all builders. The report has at length been embodied in the shape of a memorandum addressed to builders and others concerned and was issued in February last.

The increasing number and importance of electrical generating works and the well recognised danger which threatens those who work in them have engaged the serious attention of the department but up to the present time the chief work done by the inspectors has apparently been confined to the southern division of England—at any rate the report of the chief inspector for the southern division is the only one which is specifically referred to in the chief inspector's prefatory remarks on the question. The whole subject is, of course a comparatively new one and it may be of use here to describe in brief outline the way in which the electrical industry became to some extent under the control of the department. It need hardly be said that the generation of electricity as a commercial enterprise was not foreseen by those who framed the earlier Factory Acts, and finally electrical works only came within the purview of the factory inspectors because they were places in which a dangerous trade was being carried on A committee was appointed to advise as to the regulations which should become obligatory in factories carrying on this trade and certain recommendations were drawn up and the attention of the owners and managers of electrical works was drawn to them.[2] In future there will be no difficulty as to the question as to whether electrical generating works do or do not fall within the scope of the Factory Acts for the matter is made clear in the Act of 1901 which defines as a factory any place in which electrical energy is generated or transformed—the only exception being that made in the case of private houses. The report of Mr W D Cramp the superintending inspector for the southern division of England, contains information derived from London Southampton and Bristol, and in addition some valuable notes by Mr Fearon (*peripatetic inspector*) who visited a large number of electrical generating works to inquire and to report as to how far the recommendations of the Dangerous Trades Committee had been carried out. The result of his visits was on the whole satisfactory He found that the electrical engineers welcomed the recommendations as being thoroughly practical and that in a very great many cases they had as far as possible, adopted them in the management of plant which had not been designed with a view to comply with them Mr Fearon adds three suggestions of his own. The first two of these appear to be of special value and the first at least is so easy of application and so obvious in intention that there seems to be no reason why it should not be immediately and universally adopted It may perhaps be useful to give these recommendations *in extenso* in the hope that they may be seen by some engineers concerned in the work who may not have leisure to wade through a big un indexed blue-book.

1. All spanners or other tools for work on or near live metal should have moulded handles and box spanners only should be used
2. The cases of all instruments to which there are high pressure connexions should be earthed for the same reasons as transformer cases are.
3. Experienced men only should be allowed to work in sub-stations or behind switch boards. (P 30)

In the matter of fire prevention it is satisfactory to record the fact that the Chief Inspector reports that there is a steady advance in the direction of securing adequate provision of the means of escape.

A great part of the work of the factory inspectors consists in investigating the conditions under which the more dangerous trades are carried on. There are at the present time 26 codes of special rules in force for the regulation of these industries, and during the year 1901 7833 works existed in which definite rules were enforced. The number of trades placed under special regulations increases year by year and the number of works to be visited increases also

During the year 1901 only four cases of phosphorus poisoning occurred in connexion with the manufacture of lucifer matches and in one of these cases the patient had ceased to work at this trade for more than a year The diminution in the number of these distressing cases is most marked, it is chiefly due to change in the processes of manufacture of matches. The poisonous lucifer match is happily almost extinct.

Twelve cases of arsenical poisoning were notified and of these no less than seven occurred in galvanising works

An increase in the number of cases of anthrax has of late years caused special attention to be directed to discover the source of origin of the infection—that is to say from what part of the world the diseased skins are obtained. Special rules were enforced in factories in which skins were handled in the years 1898–99 and in 1901 a conference was held at the Home Office with the employers of the labourers engaged in the trade. A new code of rules was drawn up and these are now in force in 122 works in which there is danger of infection from hides and skins The result of careful inquiry showed that the chief places from which infected skins were imported were China and the west coast of India.

It may be remembered that the factory report for the year 1900 contained an account of a special investigation made in aerated water factories to determine the cause of the frequency of the accidents which occurred in them It was found that many of the operatives did not use the eye-guards which were provided for them and that many of the workers, especially the East Anglians, complained that the guards were injurious to the sight. Careful inquiry proved that the supposed ill effects of the guards had no basis in fact. The inspectors of factories therefore received definite instructions to insist that the rules drawn up for the protection of the workpeople should in this as in other cases be rigidly enforced.

The factories in which wall papers are made have been conducted under voluntary regulations since September 1901 The report on this trade which was made by Commander Smith was printed in the annual report for the year 1900 The fact that those engaged in the business agreed to the regulations without proceeding to arbitration was doubtless due to a great extent to the tact displayed by this officer The number of factories is not great—22 in all—and *it is extremely satisfactory that the rules have been adopted* without the exercise of compulsion and that those responsible for the business are alive to the advantages of efficient sanitary precautions in carrying on their trade. There is probably no branch of industry in which more real progress has of late years been made in this direction.

AT the meeting of the Gloucestershire county council held on July 7th it was reported that during the past quarter 116 samples had been analysed by the public analyst, only five of which were found to be adulterated.

DINNER OF THE INCORPORATED MEDICAL PRACTITIONERS ASSOCIATION —The eleventh annual dinner of this association was held on July 9th at the Holborn Restaurant, London, W C when Dr W G Dickinson (the President) occupied the chair In proposing the toast of The King Dr Dickinson said that humanly speaking the King owed his present recovery to the progress of the science and art of surgery during the last few years. In proposing the Houses of Parliament Mr George Brown said that the medical profession was very much indebted to Mr R. Ambrose, M P and other Members of the House of Commons for what they had done in amending the Midwives Bill. Mr Ambrose in response said that there was no profession which had fewer friends in Parliament than the medical profession. If the profession wanted sympathy and help in the House of Commons it ought to organise outside. He hoped that the day was not far distant when the medical profession would be as well represented at Westminster as was the legal profession. Dr F J Allan proposed the toast of the Incorporated Medical Practitioners Association " and referred to the inadequate representation of the general practitioners on the General Medical Council.

Obituary.

JOHN CURNOW, M D, F R C P LOND,

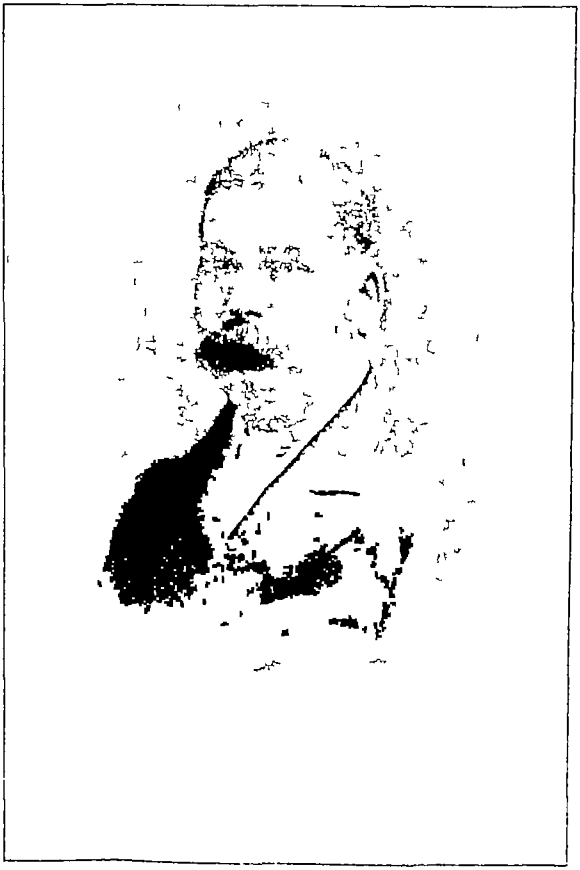
PROFESSOR OF CLINICAL MEDICINE IN KING'S COLLEGE LONDON AND PHYSICIAN TO KING'S COLLEGE HOSPITAL

DR. JOHN CURNOW, whose death was announced in our columns last week, was born at Towednack, near St Ives, Cornwall, in 1846 His father, Andrew Curnow, was a Cornish yeoman and belonged to an old Cornish family—indeed, Curnow signifies "of Cornwall," a name which is also perpetuated in Port Curnow He was very proud of this Cornish descent and throughout his life kept up his connexion with Cornwall, never failing in his summer holidays to visit Penzance, on which occasions he was largely called into consultation by the local practitioners, and indulged in long spells of his favourite amusement, sea fishing Before coming to London Curnow was a pupil with a local practitioner, a Dr Doidge, one of the leading medical men in the west of Cornwall, and thus early became acquainted with pharmacy and with general practice Often in later days he spoke of the practical advantages he had derived from the somewhat rough work that he was called upon to do That he was diligent and careful is shown by the local name bestowed upon him "Dr Doidge's young intelligent" When he came to London in 1864 he joined the medical school of King's College, gaining an entrance scholarship, the other scholars in that year being the late Professor Baxter and Professor A H Garrod, a son of Sir Alfred Garrod At the end of the first year of studentship these three were again awarded scholarships, their early association led to the formation of friendships which were only terminated by death

In 1865 Curnow matriculated at the University of London and was awarded honours, thus inaugurating a university career of almost unexampled brilliancy In 1868 at the Intermediate M.B examination he gained the exhibition and gold medal in anatomy and the exhibition and gold medal in organic chemistry materia medica, and pharmaceutical chemistry In this year also he qualified as a Member of the Royal College of Surgeons of England In 1870 he passed the M B examination and obtained the University scholarship and gold medal in medicine and the University scholarship and gold medal in obstetric medicine, together with honours in forensic medicine In 1871 he passed the M D examination and was awarded the gold medal. It is a characteristic fact that, although working to the best of his ability he never expected to take honours at these examinations and often remarked to his fellow students that he was "going to do nothing this time" This modest self-depreciation was often expressed even after the examination was completed and before the publication of the result Curnow did not say these things that they might be contradicted, modesty was a true characteristic of the man, and he really did not know what an excellent grasp he had of his subjects At the M D examination, when complimented by one of the examiners upon his diagnosis of a very difficult case, he simply remarked, "Oh, but I am plucked in the logic paper" In fact, in his own experience he showed, as he often remarked, that the best candidates do not know how well they have done, and he would add with a smile, "The converse holds good."

In 1870, with Mr J B Perrin, he was made demonstrator of anatomy at King's College under Professor Partridge, whom he succeeded in 1873, the year in which he became a Member of the Royal College of Physicians of London We mention this fact because it proves that by this time Curnow had definitely decided upon entering the medical side of his profession, and it is very rare for a physician to make a special study of anatomy Curnow held this professorship until 1896—that is to say, for 23 years—when he was elected professor of clinical medicine The methods of Partridge and Curnow presented a curious contrast, the former amused and instructed his audience at the same time, enforcing his point or fixing a fact by anecdote, by practical quotations (often diverted from their original meaning), or by some trivial joke, the latter, with what has been aptly termed "the seriousness of youth," kept rigidly to the subject, demonstrated, tabulated and catechised until he felt sure that knowledge had been transmitted As a professor of anatomy Curnow never spared himself, he multiplied lectures and demonstrations according to the needs of his class, and in the dissecting room, especially while conducting the lengthy demonstrations for the candidates for the First Fellowship of the Royal College of Surgeons of England, he acquired that personal interest in his students which led him to follow their subsequent careers with an almost paternal eye. One of the best anatomists in England, now occupying an important professorial chair of that science, writes to us as follows "Curnow was an enthusiastic teacher and a keen observer He maintained the traditio of the school so intimately associated with the research of the late Professor John Wood Amongst his mo important contributions to anatomical literature were h papers on 'Variations in the Arrangement of the Extens Muscles of the Forearm,' 'Muscular Irregularities,' ar 'Notes on Irregularities in Muscles and Nerves' He al from time to time recorded many interesting examples osseous, vascular, and muscular anomalies He had th gift of clothing the bare facts of anatomy with an interes which so impressed his pupils that many to this day wi recall his telling demonstrations and apt illustrations B more than all Curnow will ever be remembered by his friend and pupils alike for his broad minded sympathies an willingness to help where help was needed" In shor Curnow was unsparing of his own pains and sympathet with the troubles of his pupils—a combination that mak the really great teacher as well as the really fair examine The universities of London, Durham, and Victoria a different times availed themselves of his services a examiner

In 1874, when there was a vacancy at King's Colleg Hospital for an assistant physician, Dr E B Baxter an Dr Curnow were both candidates and the council solve the difficulty of making a selection between two suc men by appointing them both assistant physicians an leaving them to share the work In 1878 Curno became physician to the *Dreadnought* Seamen's Hospita and used the opportunities afforded him by the appointment to become familiar with many of the phase of tropical disease. He severed his connexion with th institution in 1897, after nearly 20 years' work, and whe he was senior visiting physician, in circumstances whic caused much controversy and which were fully reported i our columns There is no doubt that he felt keenly givin up a post which he had held so long and work whic interested him so much, but the situation, as he conceived it requiring his resignation he tendered it without hesitation In 1890 he was made physician t King's College Hospital with care of in patients As physician his skill speedily gained the confidence of hi patients, and this was deepened into affection by hi obviously genuine fellow feeling with them when in trouble In the wards he taught well, both by precept and b practice Students often marvelled at the ease, rapidity, an accuracy of his diagnosis, forgetting that his anatomical wor had cultivated in him the habit of close observation and th employment of every sense In treatment his tendency wa to avoid many of the newer remedies, but the advice tha he gave was always marked by simplicity and firmne which commanded respect and ensured confidence I prognosis he was often startling and bold One of hi friends in writing of him to us tells us how once a physicia in a provincial hospital took Curnow round his wards an was much surprised at the prognoses that he gave in man cases but some months later he had to confess that in each instance the prognosis had been verified Curnow was a man who could keep the essentials of a medical problem before him He did not lose sight of detail but he knew how to keep detail in subordination—a faculty which no doubt helped him in making his accurate forecasts. Although he never had a large consulting practice, friends, colleague and former students (the terms are synonymous) continually sought his professional aid and were invariably helped by his cheery optimism and by his readiness to sacrifice his own convenience in their service To consult Curnow was not like consulting many physicians, his personality robbed the ordeal of its solemnity There never was a man who talked and looked less like the popular conception of the resourceful physician or studious man of science, and no doubt this absence of conventionality counted for something in the fact that Curnow's position in the medical world was never that which he ought to have commanded He laughed heartily



JOHN CURNOW, M.D., F.R.C.P. LOND.
FOR 23 YEARS PROFESSOR OF ANATOMY IN KING'S COLLEGE, LONDON.

and talked freely he had no repose or dignity of manner as the phrase is generally understood but, on the other hand, he abounded in shrewdness, he spared no pains to ascertain the cause of trouble, and the dullest of his patients could not fail to see that he was receiving the most careful attention from a man who was honestly determined to help him if it were possible

Curnow was dean of the medical department at King's College from 1883 to 1896 and was unremitting in his endeavours to promote the interests of the school. It will be remembered that this period embraced the initial stages of the movement for extending the scope of university teaching in London. Curnow felt deeply on this subject, and as a member of the annual committee of the university and as representative of King's College on the committee of the deans of the medical schools he thoroughly mastered the details of a complicated subject entangled by conflicting interests, and though he spoke comparatively rarely he expressed his views very forcibly in these columns. As dean of the medical department of King's College he was perhaps too intent upon guiding matters in the directions that he believed to be right, his judgment was rarely at fault, but his administration was too zealous to be impartial He followed his own dictates of right and wrong and his evident sincerity commanded the respect of all, even of those who differed from him in opinion.

Although he wrote with facility Curnow's signed contributions to medical literature are not very numerous. In 1879—the year after he was made a Fellow of the Royal College of Physicians of London—he delivered the Goulstonian Lectures, taking for his subject The Lymphatic System and its Diseases.' These lectures were published in our columns. In the *Journal of Anatomy and Physiology* he wrote Notes of Some Muscular Abnormalities and Nerve Irregularities, and a paper on Variations in the Arrangement of the Extensor Muscles of the Forearm in the same journal contains the result of the original researches to which allusion has already been made above. He also contributed several articles to the first edition of Quain's Dictionary of Medicine, and published in our columns lectures on the Treatment of Typhoid Fever by Alcohol and the Cold Wet-pack, and on Cardiac Failure and Dilatation of the Heart. In the King's College Hospital Reports he published a most interesting historical sketch of King's College and King's College Hospital.

For more than 25 years Dr Curnow was a member of the editorial staff of THE LANCET and we were wont to rely much upon his judgment and good sense. He was a man who could maintain his own view without quarrelling with those who differed from him and as we have indicated, who could master the intricacies of a question without losing sight of the broad essentials. He was therefore, a man to whom an important subject could be relegated with a singular sense of security we felt that no pains would be spared that were necessary to make all the points clear to our readers and we knew that every side of the question would be weighed before judgment was pronounced, and that such judgment would follow the writer's sense of right and not be dictated by any private bias. He placed our readers in a position to understand all the arguments for and against the reconstitution of the University of London in a series of articles full of close reasoning and other communications to our columns upon many different aspects of medical education have been widely read and quoted. Our object and his—viz. to secure for the London student the same facilities for obtaining a medical degree that are enjoyed by the Scottish student and the student at the provincial medical schools—has not yet been attained, but, at any rate, the London student owes to the pen of John Curnow the persistent advancement of his just claims that has appeared in THE LANCET During the last decade his contributions to our columns have been much less frequent and a disinclination towards the actual labour of writing which he always admitted to be strong upon him grew still stronger. But to the day of his death he remained a member of our staff upon whose great experience we could rely for all information respecting educational questions.

The story of the life of John Curnow will be incomplete without reference to his work in Freemasonry in which he took a great deal of interest. He was initiated many years ago in the Mount Sinai Lodge, No. 121 Penzance. He was a Founder and first I G of the University of London Lodge No 2033, and subsequently passed through the chair of Worshipful Master of that Lodge. He was, moreover a Founder and one of the first Stewards of the Cornish Lodge No. 2369 of which also he was a Past Master He was made a Royal Arch Mason in the Weyside Chapter (Woking) No. 1395, and served as M E.Z. of that chapter for two years in succession and he had the honour of being a Past Grand Registrar in the Provincial Grand Chapter of Surrey By a curious coincidence the next name to his in the Deaths" in the *Times* was that of Colonel John Davis A.D C, the Provincial Grand Master of Surrey, who also died suddenly from pneumonia.

Dr Curnow who was only 56 years of age, had been in failing health for the past year and for some weeks before his death was troubled with cough and vague thoracic pain He did not observe any precaution, apparently never understanding how ill he was, and the end when it came was very sudden. He went round his wards at King's College Hospital on Friday July 4th when he was noticed to be suffering severely and complained of pain beneath the clavicles. Acute pneumonia supervened and he died from syncope on Saturday morning Dr Curnow was unmarried he leaves two sisters but no male relatives and we desire to express to those ladies our sincere sympathy with them in their great loss.

EDMUND DELAFOSSE BOND M A M.B., B CH OXON M.R.C S ENG L.R.C P LOND

WE regret to have to record the death at the early age of 28 years, of Dr E. D Bond, a young physician of great promise, who expired on July 1st at the London Fever Hospital Islington after a short illness, having contracted scarlet fever in the course of his duties He was the youngest son of the late Rev Frederick Hookey Bond M.A. who for 25 years was headmaster of the Marlborough Grammar School and of Mrs. Bond now of 16 Brock street, Bath, and was a near relative of Dr Francis Thomas Bond, honorary secretary of the Jenner Society He was educated at St. Peter's School, Weston super Mare, and at Clifton College after which he became an undergraduate of Keble College Oxford. He had a distinguished career at the University and obtained first-class honours in natural science. He next entered St. George's Hospital with an entrance scholarship and was there at the time that he fell ill, filling the post of resident assistant house officer Dr Bond was not only highly valued and respected for his ability by all his colleagues, but his amiable and gentle nature had secured for him a wide circle of attached friends.

THE SIXTH INTERNATIONAL CONGRESS OF HYDROLOGY, CLIMATOLOGY, AND GEOLOGY

DOUBTLESS it is very wrong but there is no concealing the fact that congresses, especially international congresses provide an excellent excuse for holiday excursions and picnics From this point of view the Sixth International Congress of Hydrology Climatology and Geology holds out more than usual temptations. It is to assemble at Grenoble during the first days of October Now Grenoble is not only a fine and large town but it is certainly one of the most picturesque cities in France. Just outside is the fashionable thermal station of Uriage the Moucherotte" and thence there are excursions to the valley of Graisivaudan," the valley of the Isère the celebrated monastery of the Grande Chartreuse and the abyss and bridge of Saint Bruno. The glaciers of La Meije, Aix les-Bains, and the beautiful scenery of Savoy are all close at hand. The lovers of mountainous and romantic scenery could scarcely select a more suitable base for their excursions than the town of Grenoble and as members of the Congress they will not only obtain reductions in the railway fares but various facilities for visiting places of interest. But if the pleasurable side of thi gathering is most attractive the Congress will be none the less important and interesting from the medical and the scientific point of view It will be the sixth international congress of this description that has been held. The first congress met at Biarritz in 1886. The second congress attended by the official representatives of 14 different Governments and unofficial representatives from

England, the United States, Switzerland, and other countries, met in Paris during the Universal Exhibition of 1889[1] The last congress was held at Liège in Belgium The Organising Committee of the forthcoming congress has its headquarters at Paris and its President is Dr Albert Robin who is President of the General Association of Medical Men practising in the health resorts of France Then there are Dr Leudet of Eaux Bonnes, ex President of the Hydrological Society, Professor Fredet of the Medical School of Clermont Ferrand, Dr de Ranse, and others But all communications must be addressed to the Secretary General of the congress, Dr Fernand Berlioz, École de Médecine de Grenoble, Isère, France To be a member of the congress it suffices to forward a subscription of 20 francs and all the printed reports will be sent gratuitously to the members Reports on the following subjects will be presented to the Congress and discussed The Action of Mineral Waters on the Tissues, by Professor J Renault of Lyons, Practical Methods for the Bacteriological Analyses of Mineral Waters, by Dr Bordas, Chemical Analyses of Mineral Waters and their Therapeutic Applications, by Dr Garrigon, and the Legal Measures that should be taken to Prevent Frauds in the Sale of Mineral Waters, by Dr Bouloumie These papers come under the head of "Scientific Hydrology" Then there is to be a section of "Clinical Hydrology" in which reports on the Hydromineral Treatment of Pulmonary Phthisis, by Dr Leudet and Dr Schleumer, and other papers on the Treatment of Skin Diseases, Diseases of the Digestive Organs, and of Constitutional Weakness in Children by the Use of Mineral Waters, Baths, &c., will be read A fourth section deals with Climatology and reports will be submitted on the Influence of Temperature and Altitude on the Respiratory Functions, on the Meteorological Conditions Necessary for the Installation of a Sanatorium, and on the Indoor and Outdoor Treatment at Sanatoriums Finally, there is a Geological section where the question of the preservation of mineral waters, the relations of the mineral waters of the Dauphiné and the geology of the soil, the statistics of the the mineral springs of Savoy and the Dauphiné, and the geological conditions and the origin of the mineral waters of Oriol and La Motte (Isère) will be discussed Of course, many other questions will arise out of these French papers, particularly as members representing other nationalities will also read papers It is likewise to be hoped that there will be some discussion on the sanitary condition of the various health resorts, for this is a very important question which many local authorities are apt to neglect. In view of the interest of the congress itself and the splendid opportunity of visiting some of the most celebrated and beautiful thermal stations of Europe it is very probable that the meeting will be numerously attended

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Election of President

A quarterly meeting of the Council was held on July 10th, the President, Sir Henry G Howse, being in the chair

The President reported the re election of Mr Howard Marsh, and the election of Mr John Hammond Morgan, C V O, Mr Henry Hugh Clutton, and Mr Charles William Mansell Moullin as members of Council

The President stated that Mr Moullin being fourth on the poll would be the substitute member of Council for the late Sir William Mac Cormac

Mr Marsh, Mr Morgan, Mr Clutton, and Mr Moullin were introduced, made declarations in the terms of the oath prescribed by the Charter of 1800, and took their seats as members of the Council

Sir Alfred Cooper was nominated a trustee of the Cancer Research Fund to represent the Royal College of Surgeons of England.

The Council nominated the President and Mr John Langton and Mr Henry Morris as members of the Executive Committee to be constituted under the Cancer Research Fund scheme and these members were instructed to elect in the name of the College the president and the vice-presidents of the Cancer Research Fund. Mr Henry Morris was appointed treasurer of the fund subject to the approval of the Royal College of Physicians of London

A Member of the College who had previously been struck off the Medical Register by the General Medical Council was removed from being a Member of the College.

The President stated that the committee appointed to receive a deputation from the Association of Licentiates of the Royal College of Physicians of London and Members of the Royal College of Surgeons of England would submit a report at the next meeting of the Council.

Sir Henry Greenway Howse was unanimously re elected President of the College and Mr John Tweedy and Mr A W Mayo Robson were elected Vice Presidents. The following appointments were made —Hunterian Professors Mr Charles Stewart, Mr William McAdam Eccles, and Mr Arthur Keith, Arris and Gale Lecturer Mr John Herbert Parsons, Erasmus Wilson Lecturer Dr Charles Bent Ball, Hon F R C S Eng

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD

REPORTS OF MEDICAL OFFICERS OF HEALTH

Birmingham Urban District —Dr Alfred Hill records a satisfactory diminution in the number of cases of enteric fever, a result which he ascribes largely to the provision of isolation accommodation for this disease The general death rate of the city for 1901 was 19 9 per 1000, as against an average for the last quinquennium of 20 4 The ward rates for 1901 ranged from 29 7 to 13 1 per 1000 In the three wards having the lowest general rate measles caused a death-rate of 0 28, as against a rate of 0 99 per 1000 in the three wards having the highest general death-rate Somewhat similar divergencies occurred in the case of whooping cough and diarrhœa With scarlet fever, on the other hand, the wards with the lowest general death rate yielded a higher scarlet fever case rate than the wards with the highest general death rate. The highest rate with respect to enteric fever and diphtheria was, however, in the three wards with the highest general death rate From phthisis the death rate was 2 70 per 1000 in the bad wards and only 1 14 in the good ones The cancer and heart-disease rates in the two groups were nearly identical Diphtheria antitoxin is distributed gratuitously by the sanitary authority and a very gratifying diminution of fatality rate has been apparent. The women health-visitors have, as usual, done good service in Birmingham, and amongst other things they have turned their attention to children who were sent home from school in consequence of having vermin in their hair The house accommodation for the labouring classes in Birmingham is, Dr Hill reports, quite inadequate, and he urges the town council to undertake the provision of such dwellings He has also made a representation under the Housing of the Working Classes Acts in respect of an unhealthy area possessing a population of some 2429 The mean death rate of the whole area for the last two years was 39 5 per 1000

Manchester Urban District —In his last quarterly report Dr J Niven states that during the period in question eight cows were proved to be suffering from tuberculous udders Of these eight, one was killed, two are still at the farms, concerning three there is no information available, and the remaining two were sold in the open market The want of all proper control over cows with tuberculous udders is deplorable and it is to be hoped that some reform in this direction will soon be brought about. When milk is taken from the Manchester railway stations and, on examination, is found to be tuberculous, the farm which furnished the sample is forthwith visited, and milk from cows with suspicious looking udders is examined, first microscopically, and secondly, by means of inoculation No action is taken until the milk has been definitely established to be tuberculous

Cardiff Port Sanitary District —The disinfection of the holds of ships and the destruction of rats therein are matters of such importance from the point of view of the prevention of diseases that a further reference[1] to certain e recently carried out at Cardiff with the Clayton fire-extinguishing apparatus may be useful. Dr. Edward Walford who supervised the experiments caused a number of rats confined in a cage to be placed in different parts of the hold of a ship and the sulphur dioxide generated by the Clayton apparatus was forced in at an average strength of 10 per cent. The rats placed at the bottom of the hold were killed almost immediately and those placed about three feet below the level of the deck were dead after three hours In addition to these experiments strips of fabric were soaked in liquid cultures of plague, cholera enteric fever, and anthrax organisms and were exposed in small glass dishes with loose covers After an exposure of 12 hours to the sulphur fumes all save the anthrax culture were killed From this it is inferred that all the non-sporing organisms were killed and that hence the experiments were satisfactory as sporing and harmful organisms are not likely to be encountered in practice in the holds of ships.

[1] See The Lancet, Oct 19th 1889 p 813

[1] The Lancet June 21st 1902 p 1501

Brighton Urban District —Dr A. Newsholme furnishes in his current annual report figures showing for each of the last three years the number of cases of diphtheria amongst scholars attending the several elementary schools in Brighton The board school rates for 1901 averaged from 0 2 to 7 7 per cent. of the average attendance, while the voluntary school rates ranged from 0 8 to 4 3 per cent. As to this discrepancy between the board and voluntary schools Dr Newsholme fails to find an adequate explanation in geographical distribution or in structural defects. He is of opinion that there must be differences in administration more particularly in the direction of the eagerness on the part of the school board authorities to whip up absentees, and hence the liability to bring together children suffering from slight sore-throat, &c. This is certainly an interesting speculation but we should be glad to see the comparison made in other towns before altogether accepting the thesis. We are glad to see that Brighton is in common with many other towns now affording facilities for the supply of diphtheria antitoxin and that a supply of this material can be obtained at the public health offices during the day and at the police-offices during the night. Dr Newsholme very properly urges the early administration of antitoxin, and he points out the desirability of not waiting until the nature of the disease is definitely established Certainly very valuable time may be lost by waiting and the delay is not unlikely to turn the scale between life and death. Dr Newsholme has never seen any injurious effects from 500 units administered as a prophylactic, and the Brighton Corporation has sanctioned a payment of 2*s* 6*d* for every dose thus administered at the request of the medical officer of health to children living in the same house as a child already suffering from diphtheria—that is to say if the parents are too poor to bear the expense.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8661 births and 4120 deaths were registered during the week ending July 12th. The annual rate of mortality in these towns, which had been 14 9 15 1, and 15 4 per 1000 in the three preceding weeks, declined to 14 5 per 1000 last week. In London the death rate was 14 6 per 1000 while it averaged 14 4 in the 75 other large towns. The lowest death rates in these towns were 7 6 in King's Norton 6 2 in Walthamstow 6 5 Grimsby and in Rotherham 7 1 in Great Yarmouth, 8 0 in East Ham and in Leicester 8 3 in Hornsey and 9 3 in Handsworth the highest rates were 20 1 in Bootle and in Sunderland, 21 1 in Manchester 21 9 in Newcastle-upon Tyne and 23 3 in Coventry The 4120 deaths in these towns in the same week included 533 which were referred to the principal infectious diseases against 478 and 522 in the two preceding weeks of these 533 deaths 131 resulted from whooping cough 124 from diarrhœa, 116 from measles, 54 from diphtheria, 45 from scarlet fever 45 from fever" (principally enteric) and 18 from small pox. In Hornsey Reading Leicester and four other smaller towns no death from any of these diseases was registered, while they caused the highest death rates in Norwich, Bootle Wigan, Warrington, Burnley Barrow in Furness and West Bromwich The greatest proportional mortality from measles occurred in Bristol Birkenhead Bootle Rhondda, Rochdale, Plymouth, Warrington, and Barrow in Furness from scarlet fever in Burnley Stockton-on Tees and West Bromwich, from whooping-cough in South Shields, Bootle, Barrow in Furness and Norwich from 'fever in Ipswich and Barrow in Furness, and from diarrhœa in Preston and Bootle. The mortality from diphtheria showed no marked excess in any of the large towns. Of the deaths from small pox registered during the week 13 belonged to London two to Swansea, and one each to Croydon, Tottenham and Walthamstow but not one to any other of the 76 large towns The number of small pox patients under treatment in the Metropolitan Asylums hospitals which had been 861 837 and 677 at the end of the three preceding weeks, had further declined to 579 at the end of the week, 57 new cases were admitted during the week against 107, 129 and 58 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday July 12th was 2352, against 2450 2496 and 2432 in the three preceding weeks 272 new cases were admitted during the week, against 378 276, and 255 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London which had been 173, 194 and 168 in the three preceding weeks further declined to 159 and were 12 below the corrected average number The causes of 41, or 0 9 per cent. of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham Portsmouth Leicester Bolton Salford Bradford Leeds Cardiff and in 48 other smaller towns, the largest proportions of uncertified deaths were registered in Ipswich, Liverpool and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19 2 and 16 3 per 1000 in the two preceding weeks further declined to 16 2 per 1000 during the week ending July 12th but showed an excess of 1 7 per 1000 over the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 13 5 in Aberdeen and 14 4 in Greenock to 17 9 in Edinburgh and 19 2 in Paisley The 523 deaths in these towns included 22 which were referred to measles, 15 to diarrhœa, 14 to whooping-cough, six to fever" three to diphtheria, and two to scarlet fever but not one to small pox. In all 62 deaths resulted from these principal infectious diseases in the week, against 54 57 and 66 in the three preceding weeks. These 62 deaths were equal to an annual rate of 1 9 per 1000, which was also the death rate in the week from the same diseases in the 76 large English towns. The fatal cases of measles which had been 18 15, and 13 in the three preceding weeks, again rose to 22, and included 12 in Edinburgh four in Glasgow and three in Paisley The deaths from diarrhœa which had been 17 16, and 24 in the three preceding weeks fell again to 15 and included eight in Glasgow and four in Edinburgh. The fatal cases of whooping-cough which had been 14 and 16 in the two preceding weeks, again declined to 14 and included six in Glasgow and three in Edinburgh and in Aberdeen. The deaths from scarlet fever numbered two while the fatal cases of diphtheria were three and showed a slight decline from recent weekly numbers The deaths referred to diseases of the respiratory organs in these towns which had been 101 and 87 in the two preceding weeks, further declined to 74 and were just below the number in the corresponding period of last year The causes of 19 or nearly 4 per cent. of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin which had been 17 9 19 9 and 19 1 per 1000 in the three preceding weeks, further declined to 16 9 per 1000 during the week ending July 12th During the previous four weeks the death rate had averaged 19 2 per 1000, the rates during the same period being 14 6 in London and 17 4 in Edinburgh The 123 death of persons belonging to Dublin registered during the week under notice showed an excess of 16 from the number in the preceding week, and included 17 which were referred to the principal infectious diseases, against 10 eight and nine in the three preceding weeks of these six resulted from measles, four from fever' and also from diarrhœa two from whooping-cough, and one from diphtheria, but not one from small pox or scarlet fever These 17 deaths were equal to an annual rate of 2 3 per 1000, the death-rate last week from the same diseases being 2 0 in London and 3 9 in Edinburgh. The fatal cases of fever were again four last week, and the deaths from measles, which had been four and two in the two preceding weeks, increased to six. The 123 deaths in Dublin last week included 19 of children under one year of age and 28 of persons aged upwards of 60 years The deaths of infants were one fewer than the number recorded in the previous week, while those of elderly persons showed a decrease of seven. Four deaths from violence and four inquest cases were registered, and 48, or more than one third, of the deaths occurred in public institutions The causes of two, or nearly 2 per cent of the deaths registered in Dublin last week were not certified.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE following appointments are notified —Surgeons C R Rickard to the *Moorhen* and E R L Thomas to the *Boscawen* for the *Dolphin*.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel John Martin retires on retired pay Dated June 26th, 1902.

Captain T P Jones joins at Aldershot for duty and Lieutenant M A. Cholmeley (Militia) takes over medical charge of the 2nd Infantry Brigade at Aldershot. Lieutenant Stirling takes over the charge of the Louise Margaret Hospital at Aldershot and also assumes medical charge of the troops encamped at Garrison Gorse Captain J Grech assumes medical charge of the troops at Bisley Major G F Alexander is appointed to the medical charge of the Isolation Hospital at Aldershot Major G H. Barefoot has left Aldershot for a tour of duty in the West Indies Major F J Greig is appointed Instructor at the Depôt Training School at Aldershot Captain W E P V Marriott is appointed to the medical charge of the Cavalry Brigade at Aldershot and Major R. Caldwell joins at Aldershot for the medical charge of Royal Horse and Royal Field Artillery

ARMY MEDICAL RESERVE OF OFFICERS

Surgeon Captain A. P Arnold to be Surgeon-Major

ROYAL ARMY MEDICAL CORPS (MILITIA)

The undermentioned Captains to be seconded —T W G Kelly, H E. Mortis, and J E O'Connor

IMPERIAL YEOMANRY

Duke of Lancaster's Own Surgeon Lieutenant Leonard Greenham Star Molloy resigns his commission and is appointed Lieutenant. West Somerset Charles Farrant to be Surgeon Lieutenant.

VOLUNTEER CORPS

Royal Garrison Artillery (Volunteers) 1st Cornwall (Duke of Cornwall's) Surgeon Lieutenant J Ratcliff-Gaylard, from 2nd Volunteer Battalion the Manchester Regiment, to be Surgeon Lieutenant. 1st Devonshire Oliver Eaton to be Surgeon Lieutenant 1st Norfolk Surgeon-Lieutenant A. M. Ross resigns his commission

Rifle 3rd Volunteer Battalion the Queen's (Royal West Surrey Regiment), Surgeon Lieutenant J F Hall to be Surgeon Captain 4th Volunteer Battalion the Queen's (Royal West Surrey Regiment) Surgeon-Lieutenant A. M Hickley to be Surgeon Captain 1st (Exeter and South Devon) Volunteer Battalion the Devonshire Regiment Surgeon Captain R. Pickard is borne as Supernumerary whilst serving with the Bearer Company of the Devon Volunteer Infantry Brigade. 3rd Volunteer Battalion (the Prince Albert's Somersetshire Light Infantry) Surgeon Captain F St J Kemm resigns his commission. 1st Volunteer Battalion the Worcestershire Regiment Surgeon Lieutenant J H. Wilkinson resigns his commission. 3rd Volunteer Battalion the Duke of Wellington's (West Riding Regiment) Surgeon Lieutenant D Walker to be Surgeon-Captain. 1st Volunteer Battalion the King's Own (Yorkshire Light Infantry) Surgeon-Major E Lee to be Brigade Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer to the South Yorkshire Volunteer Infantry Brigade 2nd Volunteer Battalion the Manchester Regiment The resignation of Surgeon Lieutenant J Ratcliff Gaylard, which was announced in the *London Gazette* of May 27th, 1902, is cancelled at his own request.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS)

Leeds Company Algernon Edward Luke Wear to be Lieutenant

VOLUNTEER INFANTRY BRIGADE BEARER COMPANIES.

Devon Surgeon Captain E P A Mariette, from the 2nd Volunteer Battalion the Devonshire Regiment, to be Surgeon Captain, and to command under paragraph 55A Volunteer Regulations South Wales Border The undermentioned gentlemen to be Surgeon Lieutenants John Francis Dwyer and Reginald Cowie.

THE ORDER OF ST JOHN OF JERUSALEM

The Prince of Wales, as Grand Prior of the Order of St. John of Jerusalem in England, presided at a meeting held at St. James's Palace on July 14th, when His Royal Highness presented a special medal bestowed by the Order for conspicuous service during the late war, the long service medal, and other medals and certificates for acts of gallantry in saving or attempting to save life on land The following received awards for conspicuous services to the ambulance department of the Order —

(*a*) In connexion with the mobilisation of the detachments of the St John Ambulance Brigade who proceeded on active service to South Africa, and with the despatch of ambulance material and medical comforts for the sick and wounded troops at the seat of war

Viscount Knutsford, G C M.G , Director of the Ambulance Department and Chairman of the St. John Ambulance Association

Viscountess Knutsford, Chairman of the Special Committee formed to despatch medical comforts to the brigade units

Colonel Sir Herbert C Perrott, Secretary of the Order and Chief Secretary of the Ambulance Department.

Colonel C Bowdler, Chief Commissioner, St John Ambulance Brigade

Lieutenant-Colonel C J Trimble, V D, L R.C P Edin	Deputy Commissioners St. John Ambulance Brigade
Mr Stuart C Wardell	
Lieutenant-Colonel George S Elliston, V D, M R C S Eng	
Inspector General Belgrave Ninnis, M D St. And, R.N	
Mr William Vernon, M R C S Eng	
Major Charles H Milburn, M B Durh	

Mr W J Church Brasier, Brigade Chief Superintendent

Lieutenant-Colonel Richard Holbeche, Librarian of the Order, and

Mr William G Barnes, jun, who both supervised for many months the dispatch of ambulance material and medical comforts for the troops

Mr William R. Edwards, A.C A., Accountant of the Order and Accountant and Storekeeper of the St. John Ambulance Association

Mr William H. Morgan, Chief Superintendent of the Metropolitan Corps, St. John Ambulance Brigade.

(*b*) In recognition of long and efficient service to the St. John Ambulance Association and in the St John Ambulance Brigade.

William Henry Irvin Sellers, M B Edin, Honorary Associate of the Order, Chief Surgeon, Preston Corps, St. John Ambulance Brigade.

Archibald Alexander George Dickey, M D R.U I., Honorary Associate of the Order, Honorary Surgeon, Colne Division, St. John Ambulance Brigade.

John Perry, Honorary Serving Brother of the Order, Chief Superintendent, Northampton Corps, St John Ambulance Brigade.

John George Stevenson, Private, Northampton Corps, St. John Ambulance Brigade.

Albert Edward Gordon Cox, Private, Northampton Corps, St. John Ambulance Brigade

Thomas Daniel Higgens, Private, Northampton Corps, St. John Ambulance Brigade.

Clement Heathcote, Honorary Serving Brother of the Order Superintendent, Winsford Division, St. John Ambulance Brigade

SOUTH AFRICAN NOTES

Civil Surgeon Ellenbogen is reported to be progressing favourably at Elandsfontein

THE BACTERIOLOGY OF THE SWEEPINGS COLLECTED FROM ITALIAN MEN-OF WAR.

The *Annali di Medicina Navale* for May last contains an article with tables showing the result of a bacteriological investigation of the sweepings on board a number of war vessels, the author being Dr C. M. Belli medical officer of the first class in the Italian navy The total number of germs found varied considerably not only in different ships but also in different parts of the same ship. As might be expected, the dust collected in the passages was very prolific, but strange to say fewer micro-organisms were obtainable from the men's kitchens and latrines than from anywhere else. In the officers quarters the mean number of gelatin cultured germs was 283,000 per cubic centimetre, while in the kitchens it was 45 000 and in the latrines only 15 000 Finally, Dr Belli contrasts the health of the navy with that of the army During the 20 years ending 1894 the average losses per annum per 1000 of strength were as follows —

—	Died per 1000	Invalided per 1000.
Italian Navy	4·40	6·93
Army ..	9 62	14 01

It would no doubt be a grave error " says Dr Belli in conclusion to suppose that the greater foulness of the air in land barracks as compared with its purity in war vessels is the only or indeed the principal factor to be taken into consideration when treating of the superior sanitary condition of the navy There are other and important coefficients which cannot now be discussed It nevertheless seems certain that the point in question is worthy of consideration."

VICHY WATER

Dr J Carayon, who is in charge of the military hospital at Vichy concludes a paper in the *Archives de Médecine et de Pharmacie Militaires* for June with the following list of diseases in which Vichy water may be regarded as (1) useful, (2) useless and (3) hurtful. 1. Chronic paludism palustral cachexia, dysentery (of hot climates) chronic articular rheumatism, visceral rheumatism rheumatism complicated with Heberden's nodes (except in the acute stage) intractable gout, uric gravel oxalic (phosphaturic) gravel saccharine diabetes (constitutional hepatic, nervous) anæmia (colonial) neurasthenia (when symptoms of dyspepsia are prominent) dyspepsia (especially of hepatic origin) dilatation of stomach chronic diarrhœa (muco membranous enteritis) congestion of liver hypertrophy of liver chronic hepatitis atrophic and hypertrophic cirrhosis catarrhal icterus biliary lithiasis, hepatic colic, renal lithiasis nephritic colic. 2. All rheumatic affections other than the chronic variety, wasting diabetes (so-called pancreatic, ") neurasthenia when unaccompanied by dyspeptic symptoms lesions anatomical or functional consecutive to wounds. 3. All acute affections all cachexias, save that due to paludism, pronounced senility cancer (irrespectively of site) chronic diseases of the brain or of the spinal cord, chronic pulmonary affection diseases of the heart and of the great vessels constipation (in old people due to insufficiency of muscular coat) nephritis, stricture of the urethra and its complications syphilis recent or of long standing accompanied by visceral lesions especially of the nervous centres.

MAGERSFONTEIN A PSYCHOLOGICAL STUDY OF WAR.

Among the numerous articles which have been written in connexion with the late war in South Africa we may call attention to one in the *Fortnightly* for this month on the battle at Magersfontein because it treats of it from a new and interesting point of view The article mainly deals with the effect of external conditions upon the man as distinct from the soldier and studies the psychological aspect at Magersfontein in order to emphasise a neglected factor in the equation The writer describes the effects of the climatic heat the severe thunderstorm the extreme darkness of the night and the other conditions that prevailed—all of which had a tendency towards lowering of the moral strength. He points out that, over and above the material presented on that occasion for the consideration of those who are re-organising the army there remains the conviction that with the improvement of the weapon the man who holds it becomes more, and not less, a study There was hardly a phase of possible war he asserts that was not illustrated in the two days fight at Magersfontein which presented the most impressive lesson for the future that the Boer war has afforded.

THE RUMOURED RETIREMENT OF ARMY OFFICERS.

It will be interesting to notice whether any appreciable number of medical officers will retire from the service on their return to this country from South Africa now that the war is ended. It is believed that a considerable number of officers belonging to the combatant ranks of the army are, or will be, seeking their retirement—indeed if we may credit current rumours, a big exodus is to take place. According to our service contemporary—the *Army and Navy Gazette*—the profession of arms has grown unpopular owing to the amount of adverse, and as the officers think unfair criticism to which they have been subjected. There is no doubt that much of the criticism has been unreasonable and exaggerated especially on the part of those who failed to realise the enormous difficulties of the war and who did not stop to ask themselves whether the army of any other country would have done as well or better in the circumstances.

THE WELSH HOSPITAL.

On August 14th Lord Penrhyn will unveil a memorial brass to the deceased members of the staff of the late Welsh Hospital in South Africa which is to be placed in St. David's Cathedral, and his lordship will also hand over the hospital flag to be permanently placed in the nave of the cathedral.

THE NAVAL HOSPITAL AT DARTMOUTH.

The Naval Hospital at Dartmouth will be ready for the cadets occupation at the commencement of the September term. Fleet Surgeon A. W May is to enter into occupation of his quarters immediately It is estimated that the total cost of fitting up the hospital will be upwards of £6000.

MENTIONED IN DESPATCHES.

The full name of Civil Surgeon Ellis who was brought to notice in Lord Kitchener's despatch of March 8th 1901 published in the *London Gazette* of May 7th 1901 (and in THE LANCET of May 11th 1901), is as follows —Civil Surgeon Alfred Pytches Blanchard Ellis

DEATHS IN THE SERVICES.

Deputy Surgeon General Robert Gillman Lord, I.M S (retired) at his residence Ambersgate " Chelston Torquay after a short illness in his eighty-second year

Correspondence.

THE CAUSE OF INEQUALITY OF PUPILS IN CASES OF THORACIC ANEURYSM

To the Editors of THE LANCET

SIRS,—In the elaborate, and also no doubt important paper by Dr R. C. B Wall and Dr E. W A. Walker in THE LANCET of July 12th, p 68, there is a misconception of my published opinions as to the significance of disparity of the pupils as a sign of aneurysm which it may be as well to make note of at once, because in point of fact I have no real controversy with the authors as regards either the opinions or the experimental data which they have brought to bear upon the question They attribute to me (p. 69) that I am apparently convinced that inequality of the pupils associated with thoracic aneurysm is *in all cases* due to implication of the sympathetic, and they fortify this remark by a quotation which I will not give here as it is quite clearly irrelevant and I mean to show presently that, so far from being apparently convinced as above, I have never taught, or sought to teach anything of the kind. The case which I published in 1854 was one of what we should now call spinal myosis " (although the name was not at that time in use the myosis being to a marked degree abnormal, permanent and practically unvarying over a long period of observation the opposite pupil being moreover mobile and normal in every respect. The coincidence of this condition with an aneurysm proved subsequently by post-mortem examination to have exerted permanent and destructive pressure on the lower sympathetic ganglion in the neck was a fact which had to be recorded and explained and its great importance in respect of the diagnosis of aneurysm in this situation was not only manifest but was fully discussed in reference to all the information at that time available

But the very importance of the diagnosis which might thus be supposed to emerge from a disparity of the pupils in aneurysm served to quicken my sense of the fallacies which might arise from physiological and other causes of disparity apart from aneurysm. So far from becoming "convinced that inequality of the pupils is in all cases due to implication of the sympathetic," it was not long before I became convinced of exactly the converse proposition Case after case of aneurysm was observed in detail with regard to the pupils, and it was not long before I became convinced that slight and variable degrees of disparity (which were far from being rare) were almost of no account in the diagnosis, it being a not unusual experience to have the larger of the two pupils on the aneurysmal side, and variations taking place in this respect in the same case at different times The valuable and exhaustive memoir of my friend Dr John Ogle was in this respect only unconvincing to me as it seemed to lay equal stress (or almost so) on dilatation and contraction of the pupil, the former being assumed to be (as in experiments) the result of irritation of the cilio-spinal nerves, the latter of pressure or destruction of them. It was difficult to disprove or to controvert the former mode of action from the theoretical point of view, and therefore I never attempted to do so, but as a matter of personal experience I have not succeeded in convincing myself that relative *dilatation* of the pupil is of any importance in the diagnosis of aneurysm, and *myosis* is only of importance when, as in my first case, it is manifest, permanent, and accompanied by such abnormalities of reaction as are referred to in detail in the article in Vol. VI of Clifford Allbutt's "System of Medicine," p 400 *et seq* If Dr Wall and Dr Walker will do me the favour to read carefully the cautionary statements in p 404, or the summary of my experience in p 406, they will, I think, entirely acquit me of having yielded to any such prejudice as they attribute to me It would be easy to make this clearer by quoting more in detail, but as the work in question is very accessible to almost all your readers I forbear from burdening your space

I am, Sirs, yours faithfully,

W T GAIRDNER

Edinburgh, July 15th 1902.

CIDER AND GOUT

To the Editors of THE LANCET

SIRS,—Should the gouty drink cider? This is a question often put to medical men The opinion of the authorities appears rather conflicting I myself have prescribed cider in cases of atonic gout with great benefit. I am sure that you would do a great service to us if you would let us have the benefit of your opinion on the subject.

I am, Sirs, yours faithfully,

THOMAS DOBSON, M.D St And

Windermere July 9th, 1902.

DIPHTHERIA AND ITS TREATMENT AT COLCHESTER

To the Editors of THE LANCET

SIRS,—As a year has now fully elapsed since the beginning of the epidemic of diphtheria in the borough of Colchester it may be advantageous to review this *annus mirabilis* so far as the disease in this locality is concerned in regard to its rise, progress, and decline, with any other circumstances of interest affecting it during the year Commencing in the first week of May, 1901, it has continued to the present time and no intermediate month has been free from its presence The number of notifications from the beginning of the year 1901 to its close was 287 and 43 were notified up to the end of May of that year, whilst 77 have been returned for the same period of this year, being 18 for January, February, March, and April, and 25 for May, 1901, and for this year, for January, February, March, and April, 62, and for May, 15, and only four for June, showing that the disease is now passing away Like all epidemics it was small in amount, sporadic, and of a comparatively benign character at its beginning, but speedily showed a sudden large increase, virulent in type and located in well defined special localities, in May and June, afterwards assuming in July and subsequent months a less virulent form though the numbers did not lessen till November and December

23 deaths occurred in May, June, and July out of a total of 137 notifications for that period in the borough, 111 patients were removed to the Infectious Hospital during these three months and 26 were treated at their own homes—66 had antitoxin administered with 17 deaths, 45 were treated without antitoxin with three deaths, and 26 outside the Infectious Hospital, also with three deaths Three of these deaths which occurred without antitoxin being used had the disease in a hopeless hæmorrhagic form on entering the hospital and others from organic disease either from the rapidity of the course of the malady or not being removed to the hospital soon enough for any remedy to restore the vital powers or to save life, and if antitoxin had been used in such cases it would only have increased the death-roll of those who died after receiving that remedy The total number of cases notified during the diphtheritic year commencing in May, 1901, and ending on April 30th, 1902, is 331—271 being notified from May to December, 1901, and 62 from January to April 30th, 1902, the deaths for the eight months in 1901 being 34 and those of the four months of 1902 eight, giving a total of 42 and a death rate of 12 69 for the entire period

There is probably no disease, taking it in all its phases, requiring more discrimination in its diagnosis or discretion in its treatment than this, the diseases affecting the throat being very numerous and difficult to differentiate, especially in their first stage—the time most important, especially in diphtheria, in securing the best chance of success in preventing a fatal result and a long convalescence It seems also only natural that diphtheria should be at once attacked at its point of origin and the system of cure which ignores this fact is not based on true physiological principles Remove the cause and the effect ceases, and this can easily be done at the onset and the result is everything that can be desired in a speedy removal of the dangerous poison and a short convalescence The *cilia* or brushing apparatus with which the mucous membrane of the throat and back part of the mouth is lined are soon clogged with dead matter and bacteria and their action arrested, thereby furnishing a fitting nest for the hatching of the toxins which enter the system and which give rise to all the evil consequences of the disease The first line of attack is therefore to be put in force at once by clearing the throat of these lethal products and enabling these minute organs free play in resuming their natural function of keeping the throat clean So essential are these minute organs in the animal economy and their vitality is so great that they continue in action after removal from the throat and even for three or four days after death do not lose their power of movement It is therefore a most important point in the treatment of the disease to restore their function at the soonest possible time and thus allow a means of exit to their imprisoned poisons This means of cure also lessens the chance of infection being conveyed to others, for whilst only one case of infection occurred during the 17 years previously to 1901 at the infectious hospital, seven nurses and one ward attendant were attacked by the malady during the present epidemic and the antitoxin treatment does not prevent the disease spreading to others after the patient is said to be cured

It appears derogatory to the science and practice of medicine and surgery that it should be imperative as some practitioners hold that there should be only one system of cure to a specific form of disease, that there should be no progress in the healing art, and that the most ignorant and the most experienced should be bound by a hard-and-fast rule to pursue a course of treatment which frequently entails more misery on the sufferer than the original disease itself could produce There are many mild cases of diphtheria—indeed, the majority are such—that require little treatment and some that defy all human skill, as there are cases of malignant scarlet fever and like diseases that exhibit the same tendency and are extremely fatal in the young After July 2nd, 1901, the disease was generally of a mild form and 26 cases were admitted into the hospital from that date without a single death up to the 19th and since then only occasional cases of a virulent character occurred, the cases both inside and outside the hospital being of the same description. It is a well-known law in medical science that if one disease is already in the system another as a rule is denied admittance, or if introduced its action is greatly modified or suspended till the first has run its course. Cases of scarlet fever occurred in this way and in many cases were fatal after the diphtheria

On the other hand, some children were admitted with diphtheria and in two or three days after admission chicken-pox made its appearance and though one of them had a very bad throat all recovered. Dr Jenner 100 years ago was cognisant of this fact and it is interesting to find in his biography that he was foiled in his attempt to vaccinate some patients in Colchester owing to this law His biographer relates that ' on the 15th of April 1800 His Royal Highness the Duke of York sent a message to Dr Jenner to request him to go to Colchester to vaccinate the 85th Regiment. He was under the necessity of waiting a considerable time before he could communicate the disease to anyone He found the whole of the regiment, together with the women and children labouring under the itch. He commenced his inoculations but they all proved unsuccessful. On the 2nd of May he found that one child had taken the cow pox and he adds that all the men are cured of the itch and in two days will be washed and fit for vaccination. These anticipations proved rather premature, for he observed on the 13th of May that he could not succeed in communicating the true cow pox to those whose constitutions had been under the influence of the itch His biographer states ' It appears to me of moment to allude to these assurances because they afford very convincing proofs of the truth of a doctrine which Jenner subsequently adopted and invariably maintained to the last hour of his life—namely that any cutaneous disease however slight in appearance, was capable of interfering with the regular course of cow pox and from preventing it from exercising its full protecting influence. Though Dr Jenner could not himself undertake to vaccinate the regiment at Colchester he went twice to that place to inspect the progress of the practice. It would be of immense value to mankind if such a remedy were found to give immunity from diphtheria and the same course could be pursued and with the same certainty of success as vaccination gives in small pox. Antitoxin is said to give immunity for three weeks just as we may surmise that any other disease such as chicken pox *might* have the same effect. As a prophylactic the remedy of antitoxin in mild cases is often worse than the disease and even as an adjunct to the topical treatment in producing tetanus severe urticaria, and other serious maladies it cannot be pronounced as altogether safe. Surely the resources of the human mind have not yet arrived at that state of sterility to preclude the idea of such a remedy being discovered in our own age and it is even possible that another Jenner may arise to find out a safe speedy and pleasant cure for this dreaded disease in anticipating its coming and neutralising its effects and lessening its mortality

The disease followed the usual course of an ordinary epidemic, and though a bacteriological office was instituted in September and *it was stated that the disease would be* extirpated in six weeks yet it did not have any marked decline till last month. An isolation home was also inaugurated and patients who had been treated with antitoxin in the infectious hospital but whose throats were still infected with bacteria were placed there till their throats were free from these germs. Those modes of checking the disease have been an enormous expense to the borough and cannot be considered of a therapeutic value equal to what has been claimed for them or the results have shown. The copious showers which have fallen during the past three months have been the chief cause of the decline of the disease and have been far more potent in their effects in checking it than any number of artificial schemes instituted for its suppression The science and art of surgery have no doubt advanced greatly during the latter half of last century and its boundaries have been greatly extended by the painstaking and elaborate schemes pursued in investigating the secret causes which produce and influence disease, yet the rapid progress may tempt some to cling to a theory which more extended inquiry and research *may* prove to be fallacious and thus they lead them to worship an *idolum specus* as a true divinity Antitoxin has in this way been held up as a therapeutical save-all. It is needless to say that its use given indiscriminately traverses Jenner's great law that the protective principle must be introduced into the system before the disease for which it is used breaks out

Though then, great advances have been made in the profession yet it does not appear that the ordinary life of the professional medical man has much improved In Pearson's Life of Hey who practised 100 years ago, the author throws some light on the way the world went at that time. He says that there are scarcely any opinions or modes of treatment that do not lie open to censure and animadversion no method of managing a disease of which it may not be pronounced if unsuccessful Had this been done or that left undone the issue would have been more fortunate. Hence a man disposed to detract from the merit to disparage the qualifications of his professional brethren to impute mistake or incompetence to them may easily find specious pretences for arraigning their conduct and a willing audience to listen to his ignorant, interested or malicious insinuations " Civilisation it is said, advances in a circle and it may be that the moral powers lag in the race in contrast with the intellectual.

I am Sirs, yours faithfully

Colchester July 1st 1902. GEORGE BROWN M D Glasg

PERITYPHLITIS

To the Editors of THE LANCET

SIRS,—Educated at Guy's Hospital before 1886 and familiar from my student days with the starting point of perityphlitis it has seemed to me that one meets with more cases in the post mortem room since operative treatment has become so common The few fatal cases seen by so careful an observer as Sir William Gairdner in the days before the disease was considered to be mainly surgical supports this view By making such a suggestion one does not intend to reflect upon the value of surgery in perityphlitis but the dogmas of surgery must be the result of experience, and in gaining experience it sometimes happens that the few have to suffer for the many Removal of the appendix in the quiescent stage is obviously a simple matter in the hands of an able surgeon like Sir Frederick Treves, but too often probably an operation in the acute stage, as suggested by Hilton Fagge who had ' twice seen an exploratory operation performed in suppurative peritonitis starting from ulceration of the vermiform appendix [1] may remove ' the last chance of life, ' especially when the peritonitis is not general and adhesions are commencing to localise the inflammation If surgery only for a short period in the past increased the fatality of perityphlitis one can understand how the increased opportunities thus afforded for study may have appeared almost to have led to the discovery of a new disease.

It may be added that some surgeons at least at Guy's Hospital were familiar before 1886 with the morbid anatomy of perityphlitis I remember a clinical lecture given by Sir H Greenway Howse upon perityphlitis two or three years before that date in which the origin of the trouble in the appendix was mentioned and the *rarity of foreign bodies emphasised.* The lecturer told us how when staying in a cherry growing district in France where the abundant swallowing of cherry stones was seen by their number in the fæces of peasants which were left in the fields he had been unable to find any indication that this habit of swallowing the stones led to perityphlitis being more common there than elsewhere.

I am Sirs yours faithfully

Clifton Bristol July 12th 1902. THEODORE FISHER.

To the Editors of THE LANCET

SIRS,—I hardly think that it is worth while writing and complaining about Sir Frederick Treves describing the above as a new or recent disease for by reading his lecture closely one discovers that he gives a long history to it. Perhaps on the whole Guy's men have been more alive to the important part which the appendix has played in the disease than men of other schools on account of the teaching of Addison Wilks and Fagge. What I take *Sir Frederick Treves seek* to bring out in his lecture is that surgically it is a new disease or rather that modern surgery has given a new and practical importance to it This I think is no doubt true I was at Guy's Hospital some 25 years ago and during my stay there of six years I never saw a case of appendicitis operated upon although I believe very soon indeed after my leaving Sir Charters Symonds operated successfully upon a case under the care of the late Dr Mahomed

What is important to remember still is as Sir Frederick Treves insists upon that the vast majority of cases recover and again as Sir W R Gowers points out, the severest attack is commonly the curative one Personally I have had two attacks, to describe them would take up too much of your space But let it suffice that in both, I believe, many surgeons would have operated on both occasions There is no disease about which it is so necessary to possess medical and surgical knowledge as the above, it is essentially one in which the physician and surgeon should meet, and it is often most difficult to decide which plays the more important part. I am, Sirs, your faithfully,

W J TYSON

Folkestone

To the Editors of THE LANCET

SIRS,—The correspondence on perityphlitis which has been going on in THE LANCET is one of very great importance to general practitioners. These cases present the greatest difficulty to us in dealing with them. The question which always presents itself to us is, What is the right thing to be done in the particular case before us and is it advisable to have recourse to surgical interference? Unfortnately though surgeons seem to think that this disease belongs exclusively to their domain, yet they are by no means united amongst themselves as to how to deal with it I was speaking some months ago to a well known surgeon attached to one of our largest hospitals in London on the treatment of this disease, and he was very dogmatic on the point that all cases as soon as they were diagnosed to be appendicitis should be operated upon immediately Now, however this may be in theory it does not work out in actual practice, for we see often cases presenting alarming symptoms which yet get well under ordinary medical treatment. There are times, however, when we are compelled to ask ourselves whether the case might not have been saved by operation. On the other hand, I have had occasion to wonder whether the patient might not have lived if he had not been operated upon On reading the Cavendish Lecture by Sir Frederick Treves one cannot help admiring the wide and comprehensive view he takes on the question of the surgical treatment of appendicitis, and though he lays down certain general rules as to treatment, yet, nevertheless, the result to the patient must depend on the intelligence and acumen of the medical man in attendance in advising the line of treatment to be adopted One word more. Just as there are differences of opinion among surgeons on the treatment of this disease, so also among physicians we find the same diversity One will advise salines and purges, another opium and enemata, while a third class object to drugs of any kind, but put their faith in local applications It would be well, I think, therefore, if physicians, instead of recording the antiquity of the disease, would enlighten us as to the mode of treatment they have found most successful.

HERBERT H HORDEN, M D Lond

Water lane Brixton, S W July 15th 1902

OBSERVATIONS ON DIET

To the Editors of THE LANCET

SIRS,—Dr Harry Campbell's very clear and practical answer to Dr Forbes Ross's letter really includes any answer to the strictures passed on my communication in Dr Forbes Ross's letter in THE LANCET of July 12th (p 110), so that I will not ask for space to deny the interpretation placed upon "spare diet" by him I may, however, point out (doubtless by a printer's error) that I am made to have 30 years' experience, whereas in my letter I wrote 20 years I have only been qualified 24 years, which makes me anxious at once to point out the mistake. I am, Sirs, yours faithfully,

Manchester square, W, July 13th 1902 THOMAS DUTTON

"THE ELEMENTS OF MIND"

To the Editors of THE LANCET

SIRS,—Your reviewer, after enumerating my claim to having made discoveries with regard to mind, life, the deity, and the atomic theory, says the study of such books "is weariness of the flesh It is also entirely unprofitable" Why unprofitable? *Is not* the knowledge of the composition of life a thing worth striving after? And would not a medical man be in a better position to cure the ills of life if he were better acquainted with what life really is? The question is Are my hypotheses with regard to the phenomena above mentioned sound? That I have produced both a definite and a new theory is accepted by all those—and there are many highly qualified to judge—who have studied my book sufficiently to grasp its meaning

I am, Sirs, yours faithfully,

Radnor place W, July 14th 1902. H. JAMYN BROOKS.

HORSE-DUNG IN LONDON STREETS

To the Editors of THE LANCET

SIRS,—In your issue of to day one of your annotations deals with the question of horse dung in London streets, and as a remedy you propose "some light form of mechanical scavenger" This undoubtedly would be of use. But surely the essential principle of sanitation must be prevention rather than cure, and in this instance the possibility of prevention has recently arisen in the legalisation and steadily increasing use of motor cars The horse, like the privy-midden, is a nuisance, and the ideal before the medical profession for the alleviation of this nuisance, as well as before the public for the improvement of their traffic is that by degrees the horse should be entirely ousted from the larger towns and his place taken by steam, oil, and electricity I trust that the medical profession and the medical press will do all that is in their power to promote this object, and bodies like the Betterment of London Association, whose aims have been just laid before your readers by its president, Sir W B Richmond, as well as the statutory sanitary authorities, should lay this object down as one of the most useful and practicable of their propaganda By removal of all obstacles to the use of motors, by stimulation of mechanical research and of the practical industry concerned in the development of motor cars, and by a system of licensing and heavy taxation of all horses employed in large towns this ideal is within our reach The horse is no longer a necessity, to its owner he is a luxury, and to the public he is a nuisance.—I am, Sirs, yours faithfully,

FRANCIS E FREMANTLE, M B Oxon,
M R C P Lond.,
Medical Officer of Health for the County of Hertford.

St Bartholomew's Hospital, E C, July 11th, 1902

THE LOCALLY ENGAGED CIVIL SURGEONS AND THE SOUTH AFRICAN WAR

To the Editors of THE LANCET

SIRS,—May I venture to give publicity through your columns to what is felt as a grievance by the pretty considerable number of "locally engaged civil surgeons" who have served during the war, some of them from the very commencement? The grievance is that they have been entirely passed over in the successive distributions of honours R.A.M C, of course, have had their share Medical officers in the irregular and volunteer corps have not been forgotten. English civil surgeons have been honoured in the person of at least one of their number The consulting surgeons, quite rightly, have received high distinctions Not a single decoration has been given to one of the "locally engaged" class Now these men have, in most instances, been doing exactly the same work as the irregulars and the English civil surgeons, at the same pay as the latter, at less than most of the former Many of them, at the call of patriotism, abandoned good practices when the authorities were at their wits' end to get men in the dark days of the beginning of the war Why should the fact that of two South African practitioners, one becoming a surgeon captain in an irregular corps or the C M S C and the other taking up exactly the same work without stars or rank, make such a difference? A single C M G given to one of their number would do much to allay the feeling that a deserving class of men have been badly treated

I am, Sirs, yours faithfully,

Capetown June 24th, 1902 EX CIVIL SURGEON

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

The Rebuilding of the Infirmary

A MEETING of the Manchester corporation special committee *re* the Royal Infirmary was held on July 7th, when it was by no means unanimous in its approval of the project for rebuilding on the present site There was a long discussion, but no resolution was arrived at as it was considered undesirable that the corporation should take any action before the meeting of the trustees Letters also appear in the papers criticising the scheme as to various points, such as the dise of the greatly increasing traffic, the vitiated atmosphere, nd the encroachment on the open space round the building is by no means certain that the trustees will approve of building in Piccadilly One suggestion is that the corpora on should sell the Art Gallery and Free Library and urchase the infirmary site. This, however is not a new ne. Perhaps the only new one is that the infirmary should e removed to Heaton Park, but the distance renders this reposterous Among many there is a leaning to the tanley-grove site, probably the best available. It would be ree from many of the obvious objections to the Piccadilly ite and would not be too far from the centre of the city

Small-pox at Nantwich Hospital

Our national slackness as regards vaccination is con nually being followed by its natural consequences Two ases of small pox have occurred at Nantwich workhouse nd on the second case being removed from the workhouse ospital to the urban council's temporary hospital at Ravens-moor a letter was sent to the board of guardians by the lerk to the council pointing out that the man was conveyed hither without the authority of the urban council and that hough the council wished to assist the guardians as far as hey could the accommodation was very limited and they vould not be able to take any more patients On this eing read at the meeting of the guardians one of he members made the rather serious statement that the wo patients were housed in two insanitary houses which vere dilapidated to an unfortunate degree, and life for the un ortunate nurses in charge of the place was hardly bearable." Dr T D R. Munro the medical officer of health, said that he first patient was removed to Ravensmoor by arrangement vith the urban council and he thought the best thing was lone when the second patient was taken there. He asked he guardians what provision they intended to make in the vent of a further outbreak. After considerable discussion he medical officer and the master were empowered to make rovision and were directed to apply to the urban council or permission to erect a tent on land adjoining the hospital t Ravensmoor and the clerk was instructed to call a pecial meeting to consider the matter further At a meeting of the urban council held on July 11th the tatements as to the insanitary state of the temporary hospital were contradicted by Dr Munro who said that the premises were sweet and clean and sufficient up to the present, while the surroundings were quite healthy The nurses had complained of the presence of mice and a few rats had been seen but they had not complained of the condition of the premises. All this illustrates the old adage as to one story being good till the other version is told. It looks as if a little common sense and the presence of a good cat would soon improve matters. With the strong evidence of the distance to which the infection can be carried the difficulties of providing accommodation for cases of small pox without endangering the people in the neigh bourhood are greatly increased The proposal to establish a small pox hospital meets with the strongest local opposition, naturally enough but it may happily perhaps give the inhabitants a strong inducement to welcome vaccination and revaccination The prevalence of this disease is a national humiliation, from which we should be freed in spite of the clamour of the small minority of sincere but ignorant fanatics

A Lady Sanitary Insp ctor at Hyde

At the meeting of the Hyde Council, held yesterday two additional sanitary inspectors were appointed one of them being a woman The chairman of the sanitary committee said that the female inspector would devote most of her time to the endeavour by various means to le sen the infant mor tality of the borough which in recent years has been very high Judging by the good work done by the health women' employed under the supervision of Dr J Niven in Manchester this is a step to be strongly commended The ignorance of the young mothers of the working class and the mill hands of our cotton towns as to the treatment of infants is something almost incredible and can be dealt with far more successfully by a sympathetic and intelligent woman than by a man.

Railway Servants Ambulance Instruction.

Ambulance work is popular among the railway servants of Manchester classes having been organised at many of the local railway centres one recently formed being in connexion with the Great Central Company at Ardwick Station. A course of lectures and experimental teaching have been given by Mr R. H Wright of Ardwick and 24 members of the class recently presented themselves for examination all being successful

July 15th

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Small-pox

THE epidemic of small pox at Swansea is assuming alarm ing proportions, 43 cases having been notified during the week ending July 12th on which date there were 51 patients under treatment in the small pox hospital. The population of Swansea is under 100 000 The medical officer of health (Mr Ebenezer Davies) appears to be of opinion that there is some connexion between the sudden increase in the number of cases and the crowding of the town at the time of the carnival which was held in Coronation week This view is probably correct, but there can be no doubt also that the health department of the corporation has been considerably handicapped by the evident desire of some persons in the town to minimise the serious character of the epidemic. Although such action was probably well intentioned it pos sibly had the effect of lessening the number of persons who sought revaccination as well as of engendering among the inhabitants a spirit of indifference towards the disease. Mr Davies has suggested that the board of guardians should approach the employers of labour with a view to having their workpeople revaccinated and the board has decided in addition to open more vaccination stations though it is to be regretted that the public vaccinators are to be asked to accept reduced fees Although up to the present time the accommodation at the small pox hospital has proved to be adequate to the needs of the outbreak it is probable that it will soon be overtaxed even with the additional temporary block which it is proposed to erect at once. For many years the corporation has been urged to erect a permanent isolation hospital, but from mistaken motives of economy it has neglected to do so and is now suffering for that neglect. The county assize is held alternately at Cardiff and at Swansea, and the next assize should commence at Swansea on July 28th but Mr Justice Ridley after obtaining information from the under sheriff communicated the circumstances to the Lord Chancellor with the result that it has been decided to hold the assize at Cardiff On July 8th a case of small pox was discovered at Bridgend the patient being a showman who had been in Swansea up to June 23rd and on the following day a second case was reported, the patient in this instance having recently visited Swansea Both men were removed to the small pox hospital At Brecon there have been during the past month eight cases of small pox one of which has terminated fatally All the patients were treated in the small pox hospital There has been one case of small pox at Pontardulais near Swansea the patient, a tin worker was removed to the Neath small pox hospital on July 13th. The volunteers from Brecon and from Swansea will not go into camp on Salisbury Plain owing to the presence of small pox in their district

Insanity in Glamorganshire

The two county asylums at Bridgend have accommodation for 1700 patients and serve the whole of Glamorganshire, where there was a population in 1901 of 860 800 persons In the year 1898 the corporation of Cardiff decided to build an asylum exclusively for Cardiff lunatics and plans have been prepared for an institution to accommodate 700 patients. The cost is estimated at £247 000 exclusive of the site, the boundary wall and furnishing a sum equal to £353 per bed but the administrative accommodation is sufficient for an additional 500 patients. This asylum is expected to be completed by the end of March 1904 until which date the corporation has the right to send 430 patients to the county asylums. In the report for 1901 of Dr Henry T Pringle, the medical superintendent of the county asylums he states that the proportion of pauper lunatics in Glamorganshire has increa ed from 159 per 100 000 of the population in 1891 to 318 per 100 000 in 1901. In the whole of England and Wales the increase in the same period was from 208 to 302 per 100 000 There are eight Poor-law unions in the county and in two only Merthyr and Pontardawe has there been any decrease in the proportionate amount of lunacy during the 10 years The cost of maintenance at the Bridgend asylums was 9*s* 4*d* per patient weekly, the recovery rate was 32 5 per cent. on the admissions, and the death rate was 9 8 per cent of the average number of patients resident during the year Dr Pringle deplores the fact that one fourth of the cases admitted should be due to a preventable cause—intemperance in drink—and he considers that it is disappointing that education seems to do so little towards the building up of character or the promotion of self control

Death of Mr Patrick Alexander Kelly, L R C P Edin , L R C S Irel

Mr P A Kelly, whose death occurred at Barry on July 11th after only a few days' illness, was attached to the French ambulance service in the Franco Prussian war of 1870 On the termination of the war he qualified in Dublin and in Edinburgh and subsequently practised in South Africa, where he was a justice of the peace. On returning to England he came to Barry in 1891, where he established a lucrative practice He took a prominent part in local affairs and the regard in which he was held by his fellow practitioners is shown by their electing him as their representative on the hospital committee of the district council He leaves a widow and six children

Vaccination in the West of England

At the meeting of the St Austell (Cornwall) board of guardians held on July 11th it was reported that the charges recently made against two of the public vaccinators of the union had been fully investigated by a committee appointed for the purpose which had found that the charges made in reference to one of the gentlemen were so trivial that it was not necessary to take any action In regard to the other official he had admitted various inaccuracies in the register whereby the claim of £57 was reduced to £47 These inaccuracies, he stated, were due to inadvertencies and carelessness, but the committee did not regard his explanation as satisfactory and recommended that he should be reprimanded and cautioned as to his future conduct as public vaccinator A letter was read from the public vaccinator referred to, expressing deep regret, willingness to forego the whole of the past quarter's vaccination fees, and a desire to earn back the confidence of the board The guardians after some discussion adopted the recommendation of the committee

Dorchester and Sir Frederick Treves

At the meeting of the Dorchester town council held on July 8th it was unanimously resolved that a vote of congratulation should be forwarded to Sir Frederick Treves on his elevation to the baronetage Sir Frederick Treves is a native of Dorchester and was recently presented with the freedom of the borough Mr W B Cosens, who seconded the proposal, said that he had received a communication from Sir Frederick Treves stating that he had chosen to be known as "Sir Frederick Treves of Dorchester," an announcement which was received with great applause

July 14th

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Death of Mr Joseph McNinch, M D R U I

I REGRET to announce the death of Dr Joseph McNinch, which took place at his residence, Larne, co Antrim, on July 3rd, from acute pneumonia, after a very brief illness. A member of a well known Larne family, where his ancestors had lived for several generations, Dr McNinch studied at Queen's College, Belfast, and graduated as M D of the Royal University of Ireland in 1883 Returning to his birth place he practised in Larne and enjoyed a large *clientèle* until a few years ago, when owing to failing health he was not able to do so much work. He was consulting medical officer of the urban district of Larne and his decease at a comparatively early age is a matter of deep regret He was buried on July 5th at Kilwaughter Cemetery, near Larne He leaves a widow and three children to mourn their loss

Presentation to Dr John Campbell

On July 7th, in the Samaritan Hospital, Belfast, Dr John Campbell, surgeon to that institution, was presented on the occasion of his marriage with a silver tea and coffee service by the committee, matron, and nurses of the Samaritan Hospital as a token of gratitude for his unfailing kindness and attention. Many members of the medical profession, on the invitation of the committee of the hospital, were present

Anahilt Dispensary District

Dr David Clarke Campbell has been appointed medica officer of the Anahilt Dispensary district by the Lisbur board of guardians in place of the late Dr W Thomson

Death of Mr William Warwick, M D Aberd , M R C S Eng

One of the oldest medical practitioners in Belfast, Dr W Warwick, died at his residence in that city o July 10th, at the advanced age of 76 years, surrounded b all the members of his family Obtaining the M R C S Eng in 1851 and the M D of King's College, Aberdeen, in 1860 Dr Warwick was for over 50 years a medical practitioner i Belfast where he enjoyed an extensive practice. The deceased was most kindly and genial and of rather a retiring disposition, declining on several occasions invitations to join the City Corporation of Belfast and refusing the offer of the Commission of the Peace for the city He leaves two sons and one daughter (married to Dr E C Bigger, Local Government Board medical inspector) to mourn their loss

July 15th

PARIS

(FROM OUR OWN CORRESPONDENT)

The New Maternity Hospital

M MOURIER, the director of the Assistance Publique contrived matters so that the new Maternity Hospital should be opened on June 28th which was the centenary of the School of Obstetrics The new buildings have been erected under the superintendence of the architect of the new Academy of Medicine The building consists of three blocks united by a large central gallery The plan is that elaborated by Professor Budin in 1897 The first block is for new admissions, the second for women in labour, and the third for women during the puerperium In the first block the new arrivals are put through a vigorous cleansing process and they are not allowed to pass out until the latest hygienic regulations have been duly attended to In the second block is the lying in ward, with 10 beds , it is of ample size and is beautifully lighted Here at least 3600 cases of labour per annum will be taken in hand and here the pupil midwives will undergo the practical instruction which is the necessary complement of their theoretical training Every pupil will in turn be on duty for 24 hours All the appointments of the ward are in the latest fashion and there are facilities for sterilising instruments and a plentiful supply of sterilised water both hot and cold The pupils will take their meals in the basement of this block, which is well lighted and airy, so that there may be no excuse for leaving their patients for any length of time In this block, also, is a theatre for lectures and operations In the third block are four large wards for women who have been confined, containing in all 72 beds One ward with 16 beds is for patients requiring particular care and there are also one or two private rooms for patients who for one cause or another do not wish to be seen The Tarnier ward for patients who have to be isolated has 10 beds only and is, together with its operating theatre and nursing staff cut off from the rest of the building The nurses have separate rooms which are comfortably furnished and so have the midwives The buildings are lighted throughout by electricity and the cost is 800,000 francs

The New Cochin Hospital

On July 3rd two new medical blocks were opened at the Cochin Hospital They are named after Claude Bernard and Potain respectively These buildings are the commencement of the total reconstruction of the hospital, which will be carried through as soon as funds permit. A large portion of the present buildings consists of wooden erections which were provisionally put up at the time of the war of 1870 They did well enough on an emergency but as permanent buildings they were most unsuitable, the patients suffering extremes of heat and cold, to say nothing of the buildings being infested by rats and fleas The patients will be moved into the new buildings as soon as possible. The

Claude Bernard block is made up of four wards well lighted and looking on to pretty gardens. Everything is constructed with a view to being easily kept clean. There is, moreover an amusement ward in which the walls are hung with water-colours while the games provided include draughts, lotto, and dominoes. In the ward superintendent's rooms are the poisons used—all kept in special bottles The night stools for the patients are made of painted iron and have a moveable seat which can be easily cleaned They are fitted with an attachment for a table at which the patient can eat or write in bed Plates, forks, and spoons are made of aluminium as also are the tumblers. These last-named were formerly of glass and the substitution of aluminium will effect a great saving for an enormous number used to be broken every year The arrangements for the disposal of dirty linen are excellent and there is a plentiful supply of hot water The Potain block at present consists of only one ward intended for female patients The cost of the Claude Bernard block was 400 000 francs of which 40 000 were expended on the foundations.

The Clinical Chair of Syphilis and Dermatology

The Council of the Faculty of Medicine, which has been asked to nominate a candidate for the Clinical Chair of Syphilis and Dermatology vacant, by the retirement of Professor Fournier has decided at a meeting of 36 members, by 17 to 16 votes, to send up the name of Dr Gaucher Dr Gaucher whose name has thus been submitted to the Minister concerned, is *agrégé en exercice* and physician to the St. Antoine Hospital. The 16 votes were given to M. Hallopeau who is *agrégé libre* and physician to the St Louis Hospital Three professors did not vote.

July 16th

BERLIN

(FROM OUR OWN CORRESPONDENT.)

The Illness of King Edward VII

THE news of the postponement of the coronation and of King Edward's illness was received in Berlin with great concern. The Berlin daily papers have published detailed telegraphic accounts of the case and discussed the probable course of the illness and effects of the operation Sir Frederick Treves's lecture on appendicitis which was published in THE LANCET of June 28th was translated literally by two of the leading Berlin daily journals and paragraphs from THE LANCET and the *British Medical Journal* concerning the King's illness have been frequently quoted recently in the Berlin daily papers Portraits and biographies of the King's medical attendants especially of Sir Frederick Treves (who is invariably described as "Sir Treves") and of Lord Lister were inserted in the illustrated papers and Lord Lister is generally referred to with great respect as the founder of modern surgery

The Centralisation of Nursing

The number of trained nurses has considerably increased lately 30 years ago there were scarcely any trained nurses in Berlin apart from those employed in the hospitals. Nursing at home was mostly done by untrained people or by members of religious bodies especially by the Sisters of St. Elizabeth commonly called the Grey Sisters. Nursing at that time was of course, an easy task chiefly consisting in the administration of medicine and in the preparation of food Nowadays in the era of physical treatment, when hydro-therapeutic measures massage, dietetic, and other cures are prevailing nursing is an art and has become more and more the domain of a special profession—i.e. of the trained nurse. This class now includes a lot of people some of whom belong to the religious or other associations some to institutions based on the coöperative system, and others who are quite independent Notwithstanding the great number of nurses and male attendants it is often difficult to obtain the services of one especially when the case is urgent and the help of a nurse is required at once. At times when influenza, scarlet fever &c. prevail the family medical man may telephone to a dozen institutions without being able to procure a nurse Especially is this the case where the institution has a good reputation, although nurses belonging to other institutions may still be disengaged. To avoid this inconvenience the editor of the *Deutsche Medicinische Wochenschrift* Dr Schwalbe, proposes to organise the nursing profession by instituting a central office where the public and medical men may be able to learn at any moment when nurses are temporarily unemployed. In the central office a register is to be kept where the names of all nurses whether they belong to religious or other institutions or not, are to be booked The managers or matrons of such institutions will have to inform the office every morning as to the number of nurses unemployed and to correct their statements by telephone at once when during the day a nurse has been called to a patient or has returned, any person desiring a nurse will then only have to apply to the central office. If a nurse of a certain corporation or a particular private nurse is required the office will then be able to say whether the desired nurse is available or which other nurse can be supplied A good deal of time and trouble may be saved in this way Dr Schwalbe further indicates other advantages of the system—namely that it will exercise some sort of control over the so-called "free" nurses who do not belong to any corporation These nurses, as well as nearly all the male attendants, are not under the control of a matron or a managing board and therefore though the majority are as respectable as the nurses of the corporations they may include persons of a low moral or professional standard Hitherto if such persons have neglected their duties or have behaved in an unfair way it has been very difficult to make this known to the public. When dismissed by one family they have had every chance of being employed by another on the next day it having been very unlikely that in a big place like Berlin their misdeeds would become known. Henceforth when a patient has reason to complain of a "free" nurse he will only have to inform the central office and the nurse's name will then be removed from the register Dr Schwalbe further proposes that the central office for nurses shall be in connexion with the First Aid Society This society apart from its other undertakings, has instituted an office provided with a special telephonic system whereby the public may get information at any hour of the day or night as to the number of beds at disposal in all the hospitals of Berlin and its suburbs As this office works perfectly well and is very popular the public will probably not hesitate to apply to it for nurses The First Aid Society being under medical patronage bribery and other unfair methods of the nurses to get employment will be prevented The managing board of the First Aid Society is said to agree with Dr Schwalbe's proposals. Berlin will thus be the first town to establish a central organisation including every branch of nursing

First Aid in Railway Accidents

A remarkable improvement of the accident service in the Prussian State railways has now taken place by order of the Minister of Public Works Lately there have been several instances of railway disasters where, medical aid and dressing material have not been available within a reasonable time owing to the delay in providing the necessary material and conveying it to the place of the accident. The medical men residing in the neighbourhood of the accident could thus not do very much for the immediate relief of the wounded, especially when the accident happened at some distance from a station or town whence the necessary material could be obtained The new regulations regarding railway accidents on the State railways (which include nearly 90 per cent. of the railways in general) order that in 77 stations wagons must be kept ready which are specially furnished with everything necessary for the relief of a large number of injured people. A model wagon was lately shown to a meeting of railway officials and medical men. According to a description by Dr Brähmer one of the medical officers of the State railways published by the *Aerztliche Sachverständigen Zeitung* the wagons consist of two compartments separated from each other by a wooden partition The first room is intended for dressings and urgent operations the other for the accommodation of the injured The wagon is provided with apparatus for hot water heating and ventilation, and is lighted by acetylene gas. In the dressing room there are an operating table 1 70 metres long and 0 70 broad a wash stand for the medical men, cabinets for instruments and dressing material an ice safe a steriliser and other apparatus The instruments include of course only those necessary for first aid and very urgent operations and not those for amputations and most major operations as it has been proved by careful inquiry that a well furnished hospital may be reached from any railway station within from an hour to one and a half hours The second room of the carriage contains eight stretchers for those seriously wounded and four chairs for the slightly hurt, besides a number of woollen covers, so that at least 12 disabled people may be conveyed by the wagon. The medical officers of the railways are instructed to supervise the wagons, to keep the instruments and other appliances in good order, and in case of need to see to their renewal. In the stations where the wagons are kept a number of railway servants are to be trained in first aid, and they will have to accompany the wagons when they are required, together with the railway medical officer on duty

July 14th

NEW YORK

(FROM OUR OWN CORRESPONDENT)

A Naval Medical School

A SCHOOL for naval medical officers is contemplated by Surgeon General Rixey and is to be planned after the Army Medical School founded in 1893, the school will be established at the Naval Museum of Hygiene in Washington, D C Heretofore young medical officers of the navy have received a short course of instruction in special subjects at the Naval Hospital in Brooklyn, but this is not felt to fill the need, and the new course contemplated will be pursued on a much broader basis, the new school is expected to commence its course in the fall. The plan covers two branches of work including two classes of naval officers, first, the newly appointed medical officers of the navy will here secure instruction in the proper performance of their duties, and second, medical officers of longer service will here refresh their knowledge of special branches and fit themselves for examinations upon their return from a tour of sea duty The surgeon general's plan also includes the establishment of a school, probably at the navy yard at Norfolk, Va., where instruction will be given to the enlisted men in the medical department of the navy Much time and thought have been given to these questions by a special board of medical officers who have secured information on this subject and prepared plans for the proposed institution, the model for this school is the Army School for Hospital Corps Men at Washington Barracks, D C

Bacteriological Laboratory of the United States Marine Hospital Service

Preparations are in progress for the erection of a bacteriological laboratory in Washington, D C, under the control of the Marine Hospital Service. By an Act of Congress $35,000 have been appropriated for this purpose, together with five acres of ground, being a part of the reservation now occupied by the Naval Museum of Hygiene which will be the site Heretofore experimental research has been carried on with much difficulty on the top floor of the building devoted to the administration of the Marine Hospital Service, all this work will be done in the future in the new laboratory Very wisely, the plans for the building are so drawn as to provide for future expansion, and the appropriation just made will be used for the erection of a part only of the proposed building In view of the probable expansion of its powers into a national bureau of public health, laboratory facilities such as are planned will be quite necessary to carry on properly the work of the Marine Hospital Service.

Results of Compulsory Vaccination in Porto Rico

Dr Azel Ames, commanding the United States Vaccine Corps and director of the Vaccination Department, Porto Rico, has made an interesting report on the results of vaccination in that island. In October, 1898, small pox was endemic in Porto Rico, in December it was epidemic, in January, 1899, it had "honeycombed" the island, by February there were over 3000 recent cases and the disease was spreading at a gallop In February systematic compulsory vaccination, carefully and scientifically conducted and recorded was begun simultaneousl, and with pretty equal efficiency in all parts of the island It was vigorously prosecuted for four months only, till July 1st, when 860 000 vaccinations had been made in a population of about 960,000 Of this number 87 5 per cent. were successful. The work then ceased because completed, the disease had practically disappeared, the fuel for it to feed upon had been consumed by the "head fire" of vaccination. In the two and a half years that have since passed, instead of the former annual average death rate of 621, the mortality from small pox has been but two per annum in a population of nearly a million Summing up his experience Dr Ames notes that the very remarkable and carefully recorded experiment determined conclusively several basic facts as to vaccine lymph and its use—viz. First, that vaccine lymph, especially when glycerinated and in tubes, will not retain its efficacy when exposed, even very briefly and without great variation of temperature, to change from a temperate to a tropical climate Though the reason does not appear the fact cannot be disputed and all countries in the tropical zone should produce their own virus, if so fortunate as to start a "stock." Second, that given virile initial lymph and good cattle the very best of lymph can be produced by practically the same methods in the tropics as in colder countries, provided care is taken to protect it as soon as taken and until used from alternations of temperature. Third, that the glycerinated virus has nothing to recommend it for tropical use, if it has anywhere, and that glass tubes are worse than useless Fourth, that a good, carefully kept virus has in the tropics equal if not greater activity and efficacy than that in northern latitudes, though it ought not to be kept as long Fifth, that it is much better in hot countries especially to confine the vaccination upon animals for virus to a definite number (say 20) of abrasions on each side rather than to make linear incisions and secure thereby many lines of vesicles In the first place the specific fever created is too great and is most undesirable, while the ravages of the screw worm, if it effects a lodgment in such extensive incisions, are difficult to manage Sixth, that in field work nothing is so good with which to vaccinate an animal as the ivory point, the tube being useless, and nothing is so good with which to take virus Surely nothing is so serviceable for the vaccination of the people or practicable in a hot country Seventh, there is every warrant for positively asserting that although syphilis, tuberculosis, elephantiasis, and tetanus are common in Porto Rico, in no case has it followed that any of them, or any other disease, bovine or human, was imparted to an individual by the process of vaccination With tetanus so common in the island that 818 cases occurred in seven months of 1900-1901, a single case only (in an infant) occurred after vaccination in 860,000 vaccinations and this, of course, would have occurred as readily with any abrasion

July 7th.

AUSTRALIA

(FROM OUR OWN CORRESPONDENT)

The Plague

THE bubonic plague seems to be on the wane In Sydney the authorities are hopeful that the epidemic is practically stamped out. No case has been reported for over a fortnight from fresh areas, but a few have occurred in infected ones. The health officer of the city of Sydney, Dr W G Armstrong reported to the health committee early in the month that the cleansing operations were nearly completed, the disinfected portions constituting a broad belt running through the city from north to south and including all the parts which have been shown by the occurrence of plague, either among human beings or rats, to be infected Dr Armstrong advised that the number of men employed in cleansing operations might be reduced and a few gangs retained to deal with isolated areas Rat catching is to be carried on and inspection and prosecution of householders and property owners for sanitary shortcomings will be continued, in spite of protests by citizens as to the summary methods employed In Brisbane conditions are not so satisfactory Fresh cases continue to be reported, though not to the same extent. Among the victims were the Government medical officer, Mr O J H Wray, and Dr MacLean, resident medical officer, Brisbane Hospital Mr Wray it is supposed contracted the disease through making a post-mortem examination of a plague patient. Unfortunately, his case proved very severe and ultimately fatal Dr. MacLean caught the disease from examining a patient who died from plague at the hospital gates He has recovered from the attack and is convalescent Up to date 136 cases of plague with 36 deaths have occurred in New South Wales, and 77 cases with 23 deaths in Queensland In Western Australia several cases have occurred at Fremantle with two deaths Melbourne and Adelaide remain free.

Friendly Societies in New South Wales

A special meeting of the Friendly Societies Association of New South Wales was held early in June to consider a letter from the New South Wales Branch of the British Medical Association *re* a conference between the two associations. The letter declined a conference as useless the British Medical Association considering that the Australian Natives Association was not a legitimate friendly society It was then moved that—

> The Australian Natives Association be asked to retire from the Friendly Societies Association as their aims and objects are detrimental to this association.

After some discussion, in which several members expressed approval of the motion and said that the Australian Natives Association were trying to enlist the support of working men for political purposes the motion was ruled out of order as it had not been placed on the notice paper —The forty fifth session of the grand annual moveable committee of the Independent Order of Oddfellows Manchester Unity was held in Sydney at the beginning of May The report of the delegates to the Friendly Societies Association was read and a motion was submitted that the Manchester Unity Association withdraw from the Friendly Societies Association Much discussion ensued chiefly with regard to the Australian Natives Association and its dispute with the British Medical Association. Finally the motion was lost. The following recommendation from the Inter state conference of representatives of the Order was approved

> That it is desirable wherever population in any centre will admit to establish medical institutes and dispensaries, either alone or in combination with kindred societies whereby medical men may be directly employed and medicines dispensed under the supervision of the societies.

It was thought that such action would overcome the difficulties with the British Medical Association. The President of the Friendly Societies Association was also accorded a hearing He said that one of the dangers ahead of the institution was the dispute between societies and the British Medical Association As grand secretary of one lodge and president of the Friendly Societies Association he was in receipt of frequent communications from secretaries of suburban and country lodges, to the effect that medical men in country towns were opposed to the admission of men who were in receipt of over £200 per year He would like to point out that if the British Medical Association were to become masters of the situation and they introduced the wage limit it simply meant that the friendly societies would descend into working men s benefit societies instead of representative institutions.—At the annual session of the grand council of the Protestant Alliance Friendly Society a lengthy discussion took place concerning the attendance of medical officers on members recuperating in the country Cases occurred where a member was ordered into the country by a lodge medical officer in the metropolis, and then the medical officer of the local lodge in the country would refuse to attend him. No conclusion was reached on the general question but in a specific case a motion was carried that a medical man at Newcastle be requested to put the name of a member of the metropolitan lodge on his list. —At the last meeting of the Balmain United Friendly Societies Dispensary Dr Calder was appointed medical officer A representative of the Australian Natives Association was present and referred to the trouble with the British Medical Association. It was pointed out that other lodges kept faith with their medical men, the Australian Natives Association did not. It was decided that an endeavour should be made to bring about a conference between the British Medical Association and the Australian Natives Association. This dispensary has over 3000 members on its books.

A Hospital for Consumption for Sydney

On May 16th a deputation of members of the medical profession waited upon the Treasurer of the State of New South Wales to urge the Government to take action in connexion with a hospital for consumption and especially to grant a site for the buildings. It was pointed out that some months ago a meeting was held at the Sydney town hall and one of the resolutions passed was That the medical profession should ask the treasurer to place a sum on the estimates for providing a consumption hospital." The honorary treasurer (Mr Ser) promised to do so and also suggested certain sites and desired that the medical profession would inspect them and advise as to their suitability This had been done and a portion of Crown land, 50 acres in extent, at Hornsby was considered an eminently suitable site The deputation asked if the Government were prepared to grant this land for the purpose. The Treasurer said he would personally forward the matter He saw no difficulty with regard to the land and had no doubt that a sum would be placed in the estimates for the erection of the building This announcement led to the usual outcry by the residents of Hornsby against the erection of a hospital near them

Queen Victoria Home for Consumptives

At the last meeting of the executive committee of the Queen Victoria Home for Consumptives Dr M Intyre Sinclair was appointed resident medical officer of the new sanatorium at Wentworth. Dr Sinclair is M D of Glasgow and D P H of Cambridge and has been resident medical officer at an open air sanatorium in Gloucester Tenders were accepted for the erection of the new buildings at Wentworth at a cost of £2420.

Eye and Ear Hospital Melbourne

The committee of the Eye and Ear Hospital Melbourne is anxious to enlarge the building but has no available space. The committee has been trying to obtain a piece of ground adjoining and the property of the Metropolitan Board of Works The Premier was recently asked to induce the Board of Works to give up the site in exchange for another He intimated his willingness to assist, but the Board has to build offices on the site in question and such an erection would shut out light and air from the hospital.

Albury Hospital New South Wales

Mr M O Shaughnessy one of the paid medical officers of the Albury Hospital (New South Wales) lodged a complaint against Mr A. Andrews one of the honorary surgeons to the hospital and the Government medical officer of setting the rules at defiance and reflecting by inference on the capacity of the paid medical officers. Mr Andrews explained that he was instructed by the police to attend a patient in the hospital in his capacity of Government medical officer although it was against the rules and he said that in similar circumstances he would do the same. The committee resolved

That Mr Andrews be notified that his services as honorary surgeon were no longer required at the hospital," as he had deliberately set the rules at defiance

Death of Mr Robert Dalzell Ward M.R.C.S. Eng

Mr Robert Dalzell Ward was one of the oldest residents of North Sydney where he had lived for 50 years and where he died at the age of 83 years. He arrived in Sydney in April 1852, and settled at North Shore, where he was the first, and for some time the only medical practitioner He soon acquired a very lucrative practice and endeared himself to a large circle by his largeness of heart and active sympathy He was for many years a member of the New South Wales Medical Board.

(FROM OUR OWN CORRESPONDENT)

A Naval Medical School

A SCHOOL for naval medical officers is contemplated by Surgeon General Rixey and is to be planned after the Army Medical School founded in 1893, the school will be established at the Naval Museum of Hygiene in Washington, D C Heretofore young medical officers of the navy have received a short course of instruction in special subjects at the Naval Hospital in Brooklyn, but this is not felt to fill the need, and the new course contemplated will be pursued on a much broader basis, the new school is expected to commence its course in the fall The plan covers two branches of work including two classes of naval officers, first, the newly appointed medical officers of the navy will here secure instruction in the proper performance of their duties, and second, medical officers of longer service will here refresh their knowledge of special branches and fit themselves for examinations upon their return from a tour of sea duty The surgeon general's plan also includes the establishment of a school, probably at the navy yard at Norfolk, Va, where instruction will be given to the enlisted men in the medical department of the navy Much time and thought have been given to these questions by a special board of medical officers who have secured information on this subject and prepared plans for the proposed institution, the model for this school is the Army School for Hospital Corps Men at Washington Barracks, D C

Bacteriological Laboratory of the United States Marine Hospital Service

Preparations are in progress for the erection of a bacteriological laboratory in Washington, D C, under the control of the Marine Hospital Service. By an Act of Congress $35,000 have been appropriated for this purpose, together with five acres of ground, being a part of the reservation now occupied by the Naval Museum of Hygiene, which will be the site Heretofore experimental research has been carried on with much difficulty on the top floor of the building devoted to the administration of the Marine Hospital Service, all this work will be done in the future in the new laboratory Very wisely, the plans for the building are so drawn as to provide for future expansion, and the appropriation just made will be used for the erection of a part only of the proposed building In view of the probable expansion of its powers into a national bureau of public health, laboratory facilities such as are planned will be quite necessary to carry on properly the work of the Marine Hospital Service

Results of Compulsory Vaccination in Porto Rico

Dr Azel Ames, commanding the United States Vaccine Corps and director of the Vaccination Department, Porto Rico, has made an interesting report on the results of vaccination in that island. In October, 1898, small pox was endemic in Porto Rico, in December it was epidemic, in January, 1899, it had "honeycombed" the island, by February there were over 3000 recent cases and the disease was spreading at a gallop In February systematic compulsory vaccination, carefully and scientifically conducted and recorded, was begun simultaneously and with pretty equal efficiency in all parts of the island It was vigorously prosecuted for four months only, till July 1st, when 860 000 vaccinations had been made in a population of about 960,000 Of this number 87 5 per cent. were successful. The work then ceased because completed, the disease had practically disappeared, the fuel for it to feed upon had been consumed by the "head fire" of vaccination. In the two and a half years that have since passed, instead of the former annual average death rate of 621, the mortality from small pox has been but two per annum in a population of nearly a million Summing up his experience Dr Ames notes that the very remarkable and carefully recorded experiment determined conclusively several basic facts as to vaccine lymph and its use—viz. First that vaccine lymph, especially when glycerinated and in tubes, will not retain its efficacy when exposed, even very briefly and without great variation of temperature, to change from a temperate to a tropical climate Though the reason does not appear the fact cannot be disputed and all countries in the tropical zone should produce their own virus, if so fortunate as to start a "stock." Second, that given virile initial lymph and good cattle the very best of lymph can be produced by practically the same methods in the tropics as in colder countries, provided care is taken to protect it as soon as taken and until used from alternations of temperature. Third, that the glycerinated virus has nothing to recommend it for tropical use, if it has anywhere, and that glass tubes are worse than useless Fourth, that a good, carefully kept virus has in the tropics equal if not greater activity and efficacy than that in northern latitudes, though it ought not to be kept as long Fifth, that it is much better in hot countries especially to confine the vaccination upon animals for virus to a definite number (say 20) of abrasions on each side rather than to make linear incisions and secure thereby many lines of vesicles In the first place the specific fever created is too great and is most undesirable, while the ravages of the screw worm, if it effects a lodgment in such extensive incisions, are difficult to manage Sixth, that in field work nothing is so good with which to vaccinate an animal as the ivory point, the tube being useless, and nothing is so good with which to take virus Surely nothing is so serviceable for the vaccination of the people or practicable in a hot country Seventh, there is every warrant for positively asserting that although syphilis, tuberculosis, elephantiasis, and tetanus are common in Porto Rico, in no case has it followed that any of them, or any other disease, bovine or human, was imparted to an individual by the process of vaccination With tetanus so common in the island that 818 cases occurred in seven months of 1900–1901, a single case only (in an infant) occurred after vaccination in 860,000 vaccinations and this, of course, would have occurred as readily with any abrasion

July 7th

AUSTRALIA

(FROM OUR OWN CORRESPONDENT)

The Plague

THE bubonic plague seems to be on the wane. In Sydney the authorities are hopeful that the epidemic is practically stamped out. No case has been reported for over a fortnight from fresh areas, but a few have occurred in infected ones The health officer of the city of Sydney, Dr W G Armstrong, reported to the health committee early in the month that the cleansing operations were nearly completed, the disinfected portions constituting a broad belt running through the city from north to south and including all the parts which have been shown by the occurrence of plague, either among human beings or rats, to be infected Dr Armstrong advised that the number of men employed in cleansing operations might be reduced and a few gangs retained to deal with isolated areas Rat catching is to be carried on and inspection and prosecution of householders and property owners for sanitary shortcomings will be continued, in spite of protests by citizens as to the summary methods employed In Brisbane conditions are not so satisfactory Fresh cases continue to be reported, though not to the same extent. Among the victims were the Government medical officer, Mr C J H Wray, and Dr MacLean, resident medical officer, Brisbane Hospital Mr Wray it is supposed contracted the disease through making a post-mortem examination of a plague patient. Unfortunately, his case proved very severe and ultimately fatal. Dr MacLean caught the disease from examining a patient who died from plague at the hospital gates He has recovered from the attack and is convalescent Up to date 136 cases of plague with 36 deaths have occurred in New South Wales, and 77 cases with 23 deaths in Queensland In Western Australia several cases have occurred at Fremantle with two deaths Melbourne and Adelaide remain free

Friendly Societies in New South Wales

A special meeting of the Friendly Societies Association of New South Wales was held early in June to consider a letter from the New South Wales Branch of the British Medical Association *re* a conference between the two associations. The letter declined a conference as useless, the British Medical Association considering that the Australian Natives Association was not a legitimate friendly society It was then moved that—

> The Australian Natives Association be asked to retire from the Friendly Societies Association as their aims and objects are detrimental to this association.

After some discussion, in which several members expressed approval of the motion and said that the Australian Natives Association were trying to enlist the support of working men for political purposes the motion was ruled out of order as it had not been placed on the notice paper—The forty fifth session of the grand annual moveable committee of the Independent Order of Oddfellows, Manchester Unity was held in Sydney at the beginning of May The report of the delegates to the Friendly Societies Association was read and a motion was submitted that ' the Manchester Unity Association withdraw from the Friendly Societies Association. Much discussion ensued chiefly with regard to the Australian Natives Association and its dispute with the British Medical Association. Finally the motion was lost. The following recommendation from the Inter state conference of representatives of the Order was approved

> That it is desirable wherever population in any centre will admit to establish medical institutes and dispensaries either alone or in combination with kindred societies whereby medical men may be directly employed and medicines dispensed under the supervision of the societies

It was thought that such action would overcome the difficulties with the British Medical Association. The President of the Friendly Societies Association was also accorded a hearing He said that one of the dangers ahead of the institution was the dispute between societies and the British Medical Association As grand secretary of one lodge and president of the Friendly Societies Association he was in receipt of frequent communications from secretaries of suburban and country lodges to the effect that medical men in country towns were opposed to the admission of men who were in receipt of over £200 per year He would like to point out that if the British Medical Association were to become masters of the situation and they introduced the wage limit, it simply meant that the friendly societies would descend into working men's benefit societies instead of representative institutions.—At the annual session of the grand council of the Protestant Alliance Friendly Society a lengthy discussion took place concerning the attendance of medical officers on members recuperating in the country Cases occurred where a member was ordered into the country by a lodge medical officer in the metropolis, and then the medical officer of the local lodge in the country would refuse to attend him. No conclusion was reached on the general question, but in a specific case a motion was carried that a medical man at Newcastle be requested to put the name of a member of the metropolitan lodge on his list. —At the last meeting of the Balmain United Friendly Societies Dispensary Dr Calder was appointed medical officer A representative of the Australian Natives Association was present and referred to the trouble with the British Medical Association. It was pointed out that other lodges kept faith with their medical men the Australian Natives Association did not. It was decided that an endeavour should be made to bring about a conference between the British Medical Association and the Australian Natives Association. This dispensary has over 3000 members on its books.

A Hospital for Consumption for Sydney

On May 16th a deputation of members of the medical profession waited upon the Treasurer of the State of New South Wales to urge the Government to take action in connexion with a hospital for consumption and especially to grant a site for the buildings It was pointed out that some months ago a meeting was held at the Sydney town hall and one of the resolutions passed wa That the medical profession should ask the treasurer to place a sum on the estimates for providing a consumption hospital." The honorary treasurer (Mr Ser) promised to do so and also suggested certain sites and desired that the medical profession would inspect them and advise as to their suitability This had been done and a portion of Crown land, 50 acres in extent, at Hornsby was considered an eminently suitable site The deputation asked if the Government were prepared to grant this land for the purpose. The Treasurer said he would personally forward the matter He saw no difficulty with regard to the land and had no doubt that a sum would be placed in the estimates for the erection of the building This announcement led to the usual outcry by the residents of Hornsby against the erection of a hospital near them

Queen Victoria Home for Consumptives

At the last meeting of the executive committee of the Queen Victoria Home for Consumptives Dr M'Intyre Sinclair was appointed resident medical officer of the new sanatorium at Wentworth. Dr Sinclair is M D of Glasgow and D P H of Cambridge and has been resident medical officer at an open air sanatorium in Gloucester Tenders were accepted for the erection of the new buildings at Wentworth at a cost of £2420

Eye and Ear Hospital Melbourne

The committee of the Eye and Ear Hospital Melbourne, is anxious to enlarge the building but has no available space. The committee has been trying to obtain a piece of ground adjoining and the property of the Metropolitan Board of Works The Premier was recently asked to induce the Board of Works to give up the site in exchange for another He intimated his willingness to assist, but the Board has to build offices on the site in question and such an erection would shut out light and air from the hospital.

Albury Hospital New South Wales

Mr M O Shaughnessy one of the paid medical officers of the Albury Hospital (New South Wales) lodged a complaint against Mr A. Andrews one of the honorary surgeons to the hospital and the Government medical officer of setting the rules at defiance and reflecting by inference on the capacity of the paid medical officers. Mr Andrews explained that he was instructed by the police to attend a patient in the hospital in his capacity of Government medical officer although it was against the rules and he said that in similar circumstances he would do the same. The committee resolved

That Mr Andrews be notified that his services as honorary surgeon were no longer required at the hospital as he had deliberately set the rules at defiance.

Death of Mr Robert Dalzell Ward M R C S. Eng

Mr Robert Dalzell Ward was one of the oldest residents of North Sydney where he had lived for 50 years and where he died at the age of 83 years. He arrived in Sydney in April 1852, and settled at North Shore, where he was the first, and for some time the only medical practitioner He soon acquired a very lucrative practice and endeared himself to a large circle by his largeness of heart and active sympathy He was for many years a member of the New South Wales Medical Board.

June 10th

Medical News

UNIVERSITY OF GLASGOW—The following have passed the fourth (final) professional examination for the following degrees —

M.B C.M—Thomas Small Goodwin

M B Ch.B—William Kirkpatrick Anderson William Armitage, Robert James Arthur, †Alexander Grey Banks †James Campbell Bringan, Margaret Elizabeth Bryson, *Angus Campbell, Robert Harold Campbell John Shedden Dale, Alexander Dick, Donald Douglas M.A Andrew Robertson Dow, James Drummond, †George Ferguson, John Ferguson M.A., †Eric Dalrymple Gairdner William White George John Miller Gordon John Guthrie John Andrew Hagerty †Ronald Dingwall Hodge John Brown Dale Hunter, Neil M'Coll Hutchison †Ernest David Jackson †George

Irby Wallace Alexander Brown Watt, †Joseph White, M.A., B Sc., and David Ashley Wilson

Passed with distinction—* in surgery and clinical surgery, practice of medicine and clinical medicine, and midwifery; † in surgery and clinical surgery and practice of medicine and clinical medicine ‡ in surgery and clinical surgery and midwifery; § in surgery and clinical surgery, ‖ in practice of medicine and clinical medicine, and ¶ in midwifery

University of Dublin Trinity College—At examinations held at the School of Physic, Trinity Term, the following candidates were successful —

Previous Medical Examination.

Botany and Zoology—Walter G M Anderson Edward O Stoney, Thomas J Cobbe, Robert B Wright, Alfred G Alexander, Charles T Atkinson Francis A Coppinger, Alexander L Otway, Crosbie Maurice B Talbot, John C P Beatty, Rev Thomas Brook, John W Tomb, Thomas H. Peyton, George E G Vickery Reginald Holmes, Edwin B Bate Harry Ff Johns, William Nicholson, Dudley F Torrens Thomas M Crawford, and Charles G Sherlock

Physics and Chemistry—Frank R Seymour Francis R Coppinger, Edward O Marks John D Sands, Thomas J Cobbe, Ralph S Oldham Theodore C Somerville, John W Tomb Henry D Woodroffe, Samuel G S Haughton, Gustav W Thompson Richard Connell Cecil Conyngham, John C P Beatty, Henry J Keane, Reginald Holmes, Robert B Jackson, James E MacFarlane, George E G Vickery Basil Brooke, George B M'Caul Thomas L. de Courcey Edward Gibbon Howard S Millar, Henry D Drennan, Thomas H Peyton, and Ernest C Phelan

The following prizes and scholarships have been awarded —

Prizes—Surgical travelling prize Charles A. K. Ball and special prize, Richard A Stoney

Scholarships—Anatomy and Institutes of Medicine James G Wallis (Trinity College scholarship), and John Cunningham (Stewart scholarship) Physics Chemistry, Botany and Zoology Francis O B Ellison Purser Medal in Institutes of Medicine: William J Powell Diploma in Public Health Part I Francis W Lamb

Foreign University Intelligence—*Madrid* Dr Sebastian Recaséns Gerol has been appointed to the chair of Midwifery and Gynæcology—*Munich* Dr von Kupffer, director of the Anatomical Institute, is retiring His successor will be Dr Bonnet of Greifswald, who was formerly for many years *privat docent* in Munich—*Vienna* Dr. Riehl of Leipsic has been appointed to the chair of Dermatology formerly held by the late Dr Kaposi.—*Würzburg* Professor A. von Kölliker is giving up part of his work which will be taken over by Dr Philipp Stöhr, the Professor of Anatomy

School of Medicine of the Royal Colleges, Edinburgh—At a meeting of the governing board of the School of Medicine of the Royal Colleges, Edinburgh, the secretary, Mr R N Ramsay, reported that the number of students attending the school during the winter session 1901–1902 was 1143, and during the summer session 1902 the number was 1148

University of Cambridge Long Vacation Courses, 1902—The work of the long vacation courses in pathology, public health, chemistry, and pharmacology was commenced on July 7th In the pathological department Professor G Sims Woodhead will lecture on general pathology, giving demonstrations on morbid anatomy from formalin and post mortem room specimens, while Mr T Strangeways Pigg will treat special pathology, Mr A. E Shipley animal parasites, especially those affecting man, and Dr G H F Nuttall the general and special bacteriology of infective disease Mr T Strangeways Pigg also lectures on clinical pathology for senior students only Mr J E. Purvis is giving demonstrations in elementary physical and meteorological principles and in laboratory practice in the chemical and microscopical examination of water, air, gases, foods, disinfectants &c. This course is suitable to the requirements of the Diploma in Public Health and will be given in the University chemical laboratory Professor Bradbury and Mr W E Dixon are giving a course of lectures and demonstrations in pharmacology

The Coronation Bazaar—The hospitals which minister to the needs of the sick and suffering poor of the metropolis have always been sure of Royal sympathy in their endeavours, and, as our readers well know, Her Majesty the Queen takes a special interest in hospitals for children It was, we are certain, with real pleasure that Queen Alexandra performed the inaugural ceremony at the Coronation Bazaar which was opened at the Royal Botanical Gardens on July 10th in aid of the Hospital for Sick Children, Great Ormond street, W C The weather was not at all kindly, but despite this fact large crowds assembled along the line of route from Buckingham Palace in order to gain a glimpse of the Queen and the other Royal personages [illegible] her to the bazaar The arrangement of the stalls [illegible] pretty and novel. In place of the tawdry draperies [illegible] are usually associated with affairs of this kind stalls [illegible] erected of green lattice work covered with creepers a roses, a scheme which was quite in keeping with t grounds in which the bazaar was held. A [illegible] was present and in addition to most of the leaders of socie were to be seen the faces of many well-known [illegible] and Americans, including some of the Indian [illegible] who are on a visit to this country. On her arrival [illegible] the bazaar the Queen was presented with a [illegible] of orchids by Miss Joan Lucas, [illegible] chairman of the hospital, and [illegible] than an hour in walking round the stalls and [illegible] various purchases the Royal party, which included [illegible] Victoria, Princess Christian and her daughter, Prince Henry of Battenberg, the Duke and Duchess of [illegible] naught with Princess Margaret of Connaught, the Du and Duchess of Aosta, and Prince and Princess Charles [illegible] Denmark, left the grounds Various entertainments were [illegible] progress during the three days on which the bazaar was he and several prominent members of the theatrical [illegible] gave their assistance. We understand that the hospit will benefit by a very large amount, but as the proceeds fro all the stalls have not yet been sent in it is impossible [illegible] give the exact figures

Joint Small-pox Hospitals—It is very nece sary that all towns and urban districts should be prepare to treat by efficient isolation the first case of small pox may arise in their midst. It is unnecessary to state th the majority of districts are not prepared with a suitab hospital that complies with the requirements of the Loc Government Board, and those that are so provided, or consol themselves by thinking that they are, have an old [illegible] mansion or a dilapidated wooden structure without prop and efficient sanitary arrangements and not far enoug removed from inhabited houses. To remedy this state matters Mr E Sergeant, the medical officer of health to th county council of Lancashire, has interviewed a number the urban district councils in his district, afterwards summon ing a conference of representatives of these bodies whic could conveniently combine for isolation purposes Th meeting took place in Wigan on July 10th and was we attended Mr R. Sophton, chairman of the health com mittee of the Lancashire County Council, presided, an was supported by several members of the committee. M Sergeant pointed out the necessity for early isolation the first case, he stated that the presence of the diseas within half a mile of a populous community was a sourc of danger and he mentioned the requirements of the Loc Government Board in regard to the situation of a small-po hospital He pointed out the desirability of authoritie combining for small pox purposes. In this way, he stated economy was secured for each authority as they would pa much less towards the initial structural charges and the was a reduction in the annual cost of maintenance, &c Efficiency also was secured, for a larger number of beds woul always be available for the wants of each district than coul reasonably be provided individually Then the security having the provision would be worth all the establishmen charges The proposed hospital area was comprised withi a radius of 10 miles and the population was 222,937 in th administrative county and with the county borough Wigan it was 283 701. For this 40 beds would be sufficien in the first instance, with provision for extension. Th cost exclusive of land would be £20,000 and the up-kee when not occupied would be £500 per annum, and M Sergeant estimated that with money at 3¼ per cent it would take £1600 per annum, or less than ½d. i the £ on the assessable value of the whole district for the total expenditure and repayment of capita in 30 years with interest. A similarly combined distric exists at Elswick and it was stated that a penny per head the population per annum was ample for the purpose. A interesting discussion followed, but as the representative were only empowered to hear Mr Sergeant's views the promised to report to their authorities and the meeting wa adjourned to a date in August The [illegible] area suggested by Mr Sergeant, is a [illegible] tion purposes. The urban district [illegible] under the Isolation Hospitals Act, [illegible] an advantage for them to do so, [illegible] advantage also if the county borough of Wigan will join the combination.

IN Devonport dockyard men are in future to be employed only on condition that they are revaccinated

DONATIONS AND BEQUESTS —The Samaritan Free Hospital has received a grant of 30 guineas from the Corporation of the City of London

PRESENTATIONS TO MEDICAL MEN —At the meeting of the St. Austell board of guardians held on July 11th the guardians presented Mr William Mason, L.R.C.P L.R.C.S Edin. district medical officer with a marble and bronze clock and ornaments on the occasion of his marriage. The chairman (the Rev H. N Purcell) in making the presentation, said that the guardians regarded Mr Mason as an old friend and that he was known throughout the union for his kindness to the poor —Mr J E Richards, M R.C.S Eng L.R.C P Lond., assistant surgeon to the Pentoe collieries, has been presented with a gold watch and chain on the occasion of his leaving the district.

ST THOMAS'S HOSPITAL MEDICAL COLLEGE —The prizes gained by the students successful at the examinations held during the past winter session were distributed on July 10th by Sir Henry F Norbury K.C.B Director General of the Medical Department of the Royal Navy The chair was taken by Mr J G Wainwright J P treasurer of the hospital. Sir Henry Norbury subsequently referred to the question of the disposition of the medical officers on the eve of a naval action and considered that it might be advisable to leave a few on board the fighting ships and remove the others to the hospital ships who would return fresh after the fight. He acknowledged the deep debt of gratitude that the navy owed to St. Thomas's Hospital which had produced many distinguished naval men and he invited the attention of young medical men to the advantages of the Medical Department of the Royal Navy as a career among which he said were provision for the present and for old age, no working expenses and little or no nightwork.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

The Midwives Bill

THIS Bill has now passed through all its stages in the House of Lords and has been returned in its amended form to the House of Commons in order to be dealt with there.

Mine Accidents

The Home Secretary has decided to appoint a departmental committee to inquire into accidents in mines arising from the use of electricity

HOUSE OF COMMONS

THURSDAY JULY 10TH.

The Metropolitan Police Head-dress

Mr RITCHIE, in reply to Mr REGINALD LUCAS said that the question of supplying the Metropolitan Police with a special head-dress during very hot weather had been the subject of consideration on many occasions but it had not been found possible to provide a substitute for the helmet at present in use which would afford better protection both from heat and from blows.

Transport for Small-pox Cases in London

[illegible] transport; whether any estimate of the cost had been submitted by the ambulance committee or the Asylums Board; and whether, having regard to all the circumstances the Local Government Board would abstain from sanctioning these proposals until the councils of the metropolitan boroughs had been consulted —Mr LONG replied I have seen reports of the ambulance committee of the Metropolitan Asylum District bearing on these matters, but no proposals on the subject have been submitted to me by the managers As I understand no definite decision has been arrived at by them. In the event of any application being made to me for sanction to proposals of this kind I should not fail to give careful consideration to the various interests involved but until the proposals are before me I could not say what course I should adopt with regard to them.

The Employment of Children

Mr RITCHIE asked leave to introduce a Bill to make better provision for regulating the employment of children. He explained that the measure in the main embodied the recommendations made by the departmental committee which last year inquired into this subject. He had no hope of being able to get the Bill passed during the present session but he introduced it in order that those who were interested in the matter might ascertain and have an opportunity of studying the proposals of the Government Power was given to county councils and borough councils to regulate by by-laws the employment of children Of course those by laws would not apply to children already protected in their employment by the Factory Acts and the Mines Act. The making of the by-laws was entirely at the option of the councils but when made they would require the sanction of the Home Office before they could come into operation and the Home Office before giving its sanction would ascertain the local opinion with regard to the by laws It was proposed to prohibit the employment of children in carrying weights which were injurious to health and also in other occupations likely to be injurious to life limb, or health —Sir WALTER FOSTER congratulated the Home Secretary on having brought forward legislative proposals on this subject For some years he said children in this country had been employed in conditions conducive neither to health nor to morality

Leave was given and the Bill was introduced and formally read a first time.

Work in the Fruit preserving Trade

Mr TALBOT moved that the special order of the Secretary of State for the Home Department dated June 17th 1902, prescribing conditions for the fruit-preserving trade be annulled He explained that he made this motion in order to take exception to the sixth section only of the order which regulated the hours of girls under 16 years of age He submitted that the age limit should be 18 years.—Mr TENNANT said that he would rather see the whole order sacrificed than sanction this section under which young girls and women might be worked for 22 hours out of the 24 —Mr RITCHIE, in reply said that the order was applicable to the jam trade only in the fruit season of June July August and September and if the motion were adopted the industry would be carried on during the present season under no regulation whatever His right hon friend must remember that this was an entirely new departure and that before the Act of 1901 there was no limitation at all of the hours of labour in these factories. He had now made regulations both as to hours of labour and as to sanitation which he hoped would result in considerable improvement but he had felt bound to proceed tentatively in this matter He would point out that the order provided that a register must be kept in these factories which would be useful in showing whether at a later date the Home Office would be justified in making the rule more drastic. His right hon friend might feel certain that he would watch the operation of the order with the greatest care and would do his best at a future time to deal with any such scandals as those which he anticipated might possibly arise. He hoped he would not press his motion.—The motion was carried to a division and defeated by 63 against 76 votes.

FRIDAY JULY 11TH.

Enteric Fever among the Troops in South Africa

Sir WALTER FOSTER asked the Secretary of State for War whether he would state the total number of deaths from enteric fever amongst our troops in South Africa from Oct. 11th, 1899 to Oct 10th, 1900 the first year of the war; from Oct. 11th 1900 to Oct. 10th 1901, the second year of the war; and from Oct 11th 1901 to May 31st, 1902, when the war ended; and what had been the mortality from enteric fever per 1000 mean strength during these periods.—Mr BRODRICK replied: The statistics are as follows:—

	Deaths		Rate per 1000
Oct. 13th, 1899 to Oct. 12th 1900 ..	3774	.. ..	20 07
Oct. 13th 1900 to Oct 11th 1901 ..	2561	.. ..	10·63
Oct 12th, 1901, to May 30th 1902 ...	1656	...	6 84

London Water Question.

Sir M BHOWNAGGREE asked the President of the Local Government Board whether sub-clause 6 of Clause 15 of the London Water Bill which was inserted by the Joint Committee would have the effect of preventing any equalisation of water charges —Mr LONG replied, I think not The Water Board will acquire all the rights and powers of the several water companies and with a view to the equalisation of the water charges they will be able to alter within the limits prescribed by the Acts relating to any particular company the rates now charged by that company for the supply of water subject to this, that [illegible]

the Government, opposed the amendment arguing that the Water Board to be successful must have charge of the financial arrangement —After the amendment had been discussed at considerable length it was rejected by 192 against 101 votes

MONDAY JULY 14TH

Postmen and the Hot Weather

Mr ARTHUR LEE asked the Secretary to the Treasury as representing the Postmaster-General, whether he would consider the advisability of providing postmen with lighter clothing and head gear during the present hot weather —Mr AUSTEN CHAMBERLAIN replied: Postmen [illegible]

is necessary

The Preservatives Question.

Mr LAMBERT asked the President of the Local Government Board whether his attention had been called to a circular dated June 10th which had been issued by the sanitary authority of the borough of Eastbourne setting forth the recommendations of the Preservatives Committee and expressing the intention of that authority to act upon them whether seeing the division of opinion that existed as to the practicability of the adoption of those recommendations, he could issue a circular to public authorities recommending them to await the decision of the Government before adopting them as a basis of procedure and whether he could inform the House when he proposed to deal with the subject —Mr LONG replied I have seen a copy of the circular referred to in the question I am not at present in a position to make any statement as regards legislation on the subject of the report of the Preservatives Committee I have no power to require the adoption of any particular course by local authorities with respect to the enforcement of the law as to food adulteration and it does not appear that there would be any advantage in my issuing a circular as suggested

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office directed to the Sub-Editor, not later than 9 o clock on the Thursday morning of each week, for publication in the next number*

DEATHS

EDWARDS —On July 9th at Eastbourne, John Augustus Edwards M R C S Eng L S A aged 90 years

McKENNA —On July 4th at Bayonne France Cornelius John McKenna Surgeon Lieutenant Colonel I M S retired, aged 60 years

STIVEN —On July 12th at Manor Lodge, Harrow, E W F Stiven, M D Edin in his 51st year

N.B —A fee of 5s is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

THE KING AND THE QUACK

IN a note at p 128 of THE LANCET of July 12th 1902, we referred under this heading to an article which seemed to us not only foolish but dangerous published in a London newspaper and entitled: How the King might have been Cured without Operation". Since then our attention has been called to the same article or substantially the same appearing again under the name of Mr T R Allinson in a country newspaper the *Blackburn Weekly Telegraph* together with copious advertisements of medical" books written by Mr Allinson and of an infants food and a non intoxicating beverage put on the market by the same person. In a column entitled: Hints on Health," presumably written by Mr Allinson certain answers to correspondents contain many recommendations of the compounds advertised The editor of the *Blackburn Weekly Telegraph* seems to be an easy going person but we must repeat what we have already said that if this sort of balderdash written by Mr Allinson about his ability to cure the King without operating results in poor dupes going to him for treatment the newspaper which publishes his rubbish incurs a grave moral responsibility Whether persons actually suffering from severe abdominal trouble ever do go to Mr Allinson we are not aware but we note from a paragraph in another issue of the *Blackburn Telegraph* that he is willing to treat small pox but not to notify the patients as suffering from infectious disease in accordance with the Act.

ADVERTISEMENT

WE have received from a correspondent an extraordinary extract from the *Bexhill Chronicle* dated June 28th. The article is entitled Healthy Life at a Health Resort and consists of a wholesale eulogy of Bexhill founded upon an interview with Mr H H Hulbert. Bexhill Mr Hulbert is made to say "is replete with wonderful advantages for the invalid"; he has himself taken a house there in which according to the *Bexhill Chronicle* he will partially establish his own private home and found a select boarding establishment to test his opinions. Mr Hulbert we learn again from the *Bexhill Chronicle* is medical officer to the Health and Strength School medical adviser to the Dowsing Radiant Heat and Light Company lecturer on voice production and health to the teachers of the School Board for London and lecturer on the voice to the Guildhall School of Music. Let us hope that Mr Hulbert has been victimised by some enterprising reporter for certainly the things that he says, or is *reported to say in the article would seem to show peculiar ideas of* professional propriety

WHY NOT CLARET?

WE learn that His Majesty the King received the offer from various wine merchants and growers of the Bordeaux district of a thousand bottles of claret or more if so desired The bottles were not to bear any names of firms or owners of vineyards and the gift was simply intended to commemorate the Coronation It is stated that Lord Pembroke in his reply regretted that claret was not used in the hospitals of this country but that all the same he thanked the wine-growers who had made this generous offer It may be true that claret is not used in British hospitals but is there any reason why it should not be—any reason so cogent as to cause this excellent gift horse to be looked suspiciously in the *face?* Claret, by which we mean sound Bordeaux such as this wine would have been is an excellent and wholesome drink and we think that it is a thousand pities from every point of view that the generous and kindly thought of the Bordeaux growers was not more appreciated.

THE RUSTING OF INSTRUMENTS IN DAMP CLIMATES

To the Editors of THE LANCET

SIRS —Can any of your readers who have had experience of damp climates tell me of an efficient method of preserving instruments from rust other than the application of oil or greasy materials? I should be very glad of information. I am Sirs yours faithfully

June 20th, 1902. TROPICS.

THE GRADUAL DEVELOPMENT OF FAHRENHEIT'S THERMOMETRIC SCALE

IN the June number of *Knowledge* Sir Samuel Wilks gives some further particulars in continuation of his account of the origin of Fahrenheit's scale reference to which was made in THE LANCET of Feb. 22nd 1902 p. 565. He now replies to a critic whose objections to his views were mentioned in THE LANCET of May 10th, p 1369 Sir Samuel Wilks says: It is true that neither in Fahrenheit's biography or indeed in any work of the time is there any distinct account of the *rationale* of his scale; for had it been otherwise an explanation of it would have appeared in works of chemistry the authors of which profess ignorance of its meaning It is clear therefore that what is known can only be gathered by inference from writers who have interested themselves in the matter and these as far as my reading has gone have attributed to Newton the origin of the scale ...... We have only to multiply Newton's figures by eight to obtain Fahrenheit's scale The scale of the latter in his first constructed thermometer was plus 90 and minus 90 but it is not clear how this could have assisted in the framing of his subsequent scale as the numbers did not refer to freezing or boiling points That thermometer as is known he discarded and then made another taking for his fixed point the temperature of the human body This was Newton's method by *which he had worked It seems to be correctly said that Newton* was in doubt as to a fixed point for boiling for he speaks of boiling and violent boiling as if they implied different degrees of heat Newton's paper appeared in the Philosophical Transactions for 1701 and although anonymous has always been attributed to our great philosopher It is so said by Brewster by Kelvin, by Renou and others"

POROUS WALLS

To the Editors of THE LANCET

SIRS —On seeing your comment on the advantages of porous walls I was reminded that only the day before an architect of 25 years standing had informed me that however porous bricks may be they lose this property *soon after forming part of a dwelling* (whether from fungous growths or not he could not say) It would therefore be well if the builder were to test walls that have been in use for some time. If they then retained their pores although these might form inlets for fresh air one can easily picture circumstances under which they might form outlets"—or rather receptacles—for germs of scarlet fever or other exanthemata. It would be of use if this matter were worked out thoroughly in these days when the medical profession is being looked to for advice about sanatoriums &c. I am Sirs yours faithfully

MEDICAL ETIQUETTE IN THE COLONIES

WE mentioned in our issue of July 12th (p 125) that the rules governing medical etiquette are in some ways different in the colonies from those existing in this country and that it was perhaps necessary for medical men to advertise in the public press the hours at which they could be seen But however necessary this may be in sparsely inhabited countries like Australia or New Zealand we cannot excuse the practice in the case of anyone living in Bombay The following advertisement which appears in the Bombay paper the *Times of India* of June 14th and 21st is not to our minds the proper way for a *graduate of a university* to make himself known —

> Dr J M Pereira, M B C M Edin Specialist in Gynæcology Consultation from 9 A.M to 11 A M and 3 P.M to 5 P.M Beynon's Pharmacy opposite Watson Hotel."

We cannot find Dr J M Pereira's name in the current Medical Register but possibly the authorities of his university might give him a hint to withdraw his advertisements.

THE ARTIST'S BIRD AND THE PHYSICIAN'S REST

IN mediæval times the cock was highly esteemed Apart from his services in driving away lions he was like Barnes Newcome an authority upon the domestic affections and there is extant a long fourteenth-century poem wherein the domestic cock is held up as an example to parish clergy Whatever he may have been in a mediæval town the cock is a nuisance in a modern town and on July 14th Mr Val Prinsep appeared at the West London Police-court to answer a complaint by his neighbours of keeping noisy bird so as to be a nuisance Mr Prinsep lives at 1 Holland Park road and keeps fowls One of these fowls is a cock which is a veritable Tamagno amongst fowls. According to Dr Henry Mills of St. Mary Abbott's terrace it began to crow in the early hours of the morning and its voice was so powerful that it was impossible to secure any sleep. This, however, is the *métier* of the cock and was recognised by the Sarum breviary:

> "Surgamus ergo strenue,
> Gallus jacentes excitat
> Et somnolentos increpat,
> Gallus negantes arguit.
> Gallo canente spes redit."

Mr. Prinsep undertook to improve matters and the summons was adjourned. There are quite enough noises in London without having them added to by cock-crowing and Mr. Prinsep would be well advised to give up his poultry or if he sighs for the country sound of crowing he might get a hen such as that kept by Mr. Gilbert's Princess. She was a confirmed misanthrope, but liked to be awakened in mediæval fashion by crowing. Hilarion, it may be remembered, on remarking "Ah, then they have male poultry," was answered, "Not at all, the crowing's done by an accomplished hen." The female voice is softer than that of the male.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me of a home, preferably in Yorkshire or the Midlands, for a lady, 68 years of age, who suffers from an advanced stage of paralysis agitans? She suffers from insomnia and sometimes screams a good deal at night. She will be able to pay 30s. a week. I am, Sirs, yours faithfully,

G. N. EDMONDSON.

Uxbridge-street, Hednesford, Staffs, July 8th, 1902.

KNEIPP LINEN MESH.

THIS is an interesting material intended for ordinary underwear and made entirely, it is stated, from pure Irish linen yarn, a statement which is confirmed by a microscopic examination which we have made. Linen is a well known clean and healthy material but its use as underwear has been somewhat limited owing to the chilly feeling which is experienced when it is worn next to the skin. The Kneipp linen underwear, however, is free from this disadvantage. It is a knitted elastic material which, while protecting the body from cold, freely allows of the escape of perspiration. It is particularly well suited for summer wear, cool yet protective. Unlike woollen garments, it is not stained by the perspiration from the axilla, a proof that the perspiration passes freely through the material. The specimens of underclothing which we examined and tried practically were submitted to us by the York-street Flax Spinning Company of Belfast and of 2, Milk-street, London, E.C.

RELIGION AND QUACKERY.

To the Editors of THE LANCET.

SIRS,—Some weeks back I sent you an advertisement taken from the *Catholic Times* of the "Buckfast Abbey Remedies," and you commented thereon in an annotation in your issue of June 28th (p. 1846). From this week's issue of the same paper (a copy of which I send you herewith) you will see that the monks of Buckfast Abbey are not alone in allowing their "care for the souls of their fellow men to be adulterated with the desire to make money out of their bodily ailments." You will see that the Sisters of Charity at Rue St. Dominique, Paris, offer "St. Vincent de Paul's Elixir" by which anæmia, &c., is "completely cured" in 20 days—at 4s. 6d. a bottle. If this sort of thing goes *on*, would it not be well if some members of the medical profession were by way of retaliation, to announce that they were prepared to preach, hear confessions, and perform some of the other functions peculiar to the clergy? But what an outcry there would be in the "religious" world if such a "sacrilege" were committed.

I am, Sirs, yours faithfully,

July 13th, 1902.

E. J. H.

*** The monks at Buckfast Abbey are, we believe, all Frenchmen and therefore may not be aware of English prejudices on the subject of quackery. But we fancy that the medical profession in France is quite as averse to unqualified practice as is *our own*. Benedictine houses are all, we believe, autonomous and therefore the jurisdiction to interfere with the advertisements alluded to is difficult to find, but we feel sure that the Order as a whole would disapprove.—ED. L.

THE "Y" FUND.

SURGEON-GENERAL H. S. MUIR begs thankfully to acknowledge additional donations towards the above Fund from Surgeon-Major G. S. Robinson (Scots Guards) and the following officers of the Royal Army Medical Corps: Lieutenant-Colonels Morgan, D. O'Connell, and E. North; Majors H. J. Fletcher, W. O. Poole, and J. H. Curtis; and Captains J. H. E. Austin, W. D. Erskine, R. M. le H. Cooper, G. A. Moore and G. J. Stoney Archer. The fund now amounts to £433. It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly "handing on" to *confrères*). Should any reader of THE LANCET desire further particulars with a view to expressing *practical sympathy* a copy of the letter will be forwarded on application to Surgeon-General Muir, 28, Kensington gardens terrace, Hyde Park, London, W.

PHOTO-THERAPEUTIC APPARATUS.

NOW that photo-therapy is engaging so much attention a description of new and improved appliances for the purpose is not without interest. In response to an invitation we have recently inspected such apparatus made by the Sanitas Electrical Company, Limited, of 7A, Soho-square, London, W. The most important appliance amongst these specialities is perhaps the Dermo Lamp for applying the Finsen light treatment. This lamp is handy, convenient, and portable, and gives a steady discharge of ultra rays from iron points. The points when worn out are readily replaced by new ones. Water circulates through the lamp to keep the electrodes cool. On this account the transmitting tube may be pressed against the affected part of the body and with extension pieces in the shape of a speculum the appliance may be used for insertion into the vagina, rectum, or other cavities of the body. The violet light emitted is intense. Amongst the special light apparatus should be mentioned the electric incandescent bath, the arc light bath, and a number of special appliances for local illumination. The double light bath and the "Tricolour" light bath are also well designed, as are the bath apparatus for the treatment by light rays of the female genital organs and the revolving light bath chair.

◆

Mal de Mer will find in the Students' Number of THE LANCET the information which he desires with regard to medical literature. We recommend the works of Dr. Hale White and Dr. Mitchell Bruce on Pharmacology and Therapeutics respectively. Dr. Carter's Elements of Medicine, the eighth edition of which was published a few months ago and was reviewed in the columns of THE LANCET of May 24th, 1902, is a work of the scope that our correspondent desires. Messrs. Rose and Carless's Surgery is also recommended. Yanatas is unknown to us; it has not been submitted to analysis in our laboratory.

M. R. C. S.—The vacancies are advertised in the local and medical papers in Australia and New Zealand, and but rarely in our columns. But the elected persons usually send us notice of their appointments. The registration fee is 25s.

Hatter.—The symptoms may not all be due to mischievousness. We recommend that the child should be taken to a medical man, with a view, if deemed necessary, of an alienist being consulted.

Robin.—The proceeding is usual in the United States and in most English colonies, but it has never been followed in this country and we should regret to see it begun.

Alien Constant Reader can style himself with perfect propriety "Dr." when practising in this country.

Splendide Mendax.—The newspaper in question is not worth notice.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* " To THE EDITORS, and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures original articles and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed " To the Sub Editor "

Letters relating to the publication sale and advertising departments of THE LANCET *should be addressed To the Manager*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES

THE INDEX TO THE LANCET

THE Index to Vol I. of 1902, which was completed with the issue of June 28th and the Title-page to the Volume, were given in THE LANCET of July 5th

VOLUMES AND CASES.

VOLUMES for the first half of the year 1902 are now ready Bound in cloth gilt lettered, price 18*s*., carriage extra.

Cases for binding the half year's numbers are now ready Cloth gilt lettered, price 2*s* by post 2*s* 3*d*.

To be obtained on application to the Manager accompanied by remittance

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions post free, either from THE LANCET Offices or from Agents are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year ...	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed " London and Westminster Bank, Westminster Branch ") *should be made payable to the Manager* Mr CHARLES GOOD THE LANCET Offices 423, Strand, London, W C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid and continue to pay the whole of the heavy cost of postage on overweight foreign issues and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423 STRAND LONDON ENGLAND

Two Lectures

ON

INJURIES OF NERVES

Delivered at St Bartholomew's Hospital on March 19th and 21st, 1902

By ANTHONY A BOWLBY, C M G,
F R C S Eng,
JOINT LECTURER ON SURGERY

LECTURE II.[1]

Delivered on March 21st.

Suture of Nerves.

Gentlemen —The suture of nerves has been the usual practice of surgery for something like 20 years and the reason it was not adopted previously to that time was because very erroneous ideas prevailed. It was generally believed that nerves would not unite and in these circumstances, believing that no good was to be obtained by suture a divided nerve was left pretty much to itself. Then in addition, there was the fact that most wounds in those days suppurated and if you had sutures buried in such a wound the wound did not heal until the sutures came away Therefore surgeons were not at all inclined to leave silk inside a wound and silk was then practically the only material which was used. Consequently up to about 20 years ago or a little more than that nerves were not united at all by suture At the present time it is the custom to unite nerves by suture in any case where they are evidently wounded and in a person who has recently been injured The chief cause of failure of primary suture of a nerve is sepsis If a wound heals soundly and the two ends of a nerve have been coapted some union will certainly result, and you may take that as the main fact in the matter of primary suture of nerves.

Secondary Suture.

Let us pass on to consider what is to be done when a nerve has been injured and the wound has healed. In cases of this kind where the nerve is sutured by a secondary operation this operation is generally talked of as secondary suture. As far as the rules for that are concerned you may say there is only one rule—that in all cases where a wound has been inflicted and a nerve divided it should be sutured by an operation provided that that operation is reasonably feasible and is not dangerous out of proportion to the injury which the patient has suffered There are, of course places in the body where nerves may be divided, for instance deep down in the neck and where perhaps only some slight and unimportant filament has been cut, and the operation would not be worth while undertaking in such a case considering the risk and difficulty or the very slight inconvenience that the patient might suffer But putting aside such considerations you may say in general terms that the operation of secondary suture is to be undertaken whenever a nerve has evidently been divided and also in cases where you suspect its division. In cutting down upon the part in order to ascertain the extent of the injury and to approximate the nerve ends the first thing to remember is that the easiest place to find the nerve is above and below where the scar is and not at the scar For example, a very large number of persons injure the median or ulnar nerves about the wrist joint generally just above it and the commonest way is by falling upon glass or broken crockery or by putting the hand through a pane of glass In these cases it often happens that tendons are divided as well as nerves and if an operation for suture of tendons and of nerves is not undertaken at the time of the accident they become very awkwardly matted together so that it is a matter of considerable difficulty to dissect out the nerve from the scar It is much easier in these cases to make your incision sufficiently long to expose a healthy piece of nerve above and a healthy piece below tracing these towards the scar from both sides. You can then easily enough separate the nerves from the rest of the matted tissues and having separated them you can refresh the divided ends and suture them together

In many of these cases there is not too much material to spare, for the nerve ends have often become widely separated and you must consequently not sacrifice more of the nerve than need be. Do not cut off the bulb on the upper end, for it is composed of young nerve fibres Its tip merges in the neighbouring fibrous tissue of the scar, and that of course must be cut off but the upper part of the bulb of a nerve is about the best material for suturing It is composed of numerous rapidly growing nerve fibres and it holds a suture exceedingly well because it is tough and resistant. Therefore, when you have separated the two ends and are dealing with the upper end be moderate in cutting away the bulb and leave part of it. As far as the lower end of the cut nerve is concerned the whole of it is often shrunken and smaller than natural, because either it has completely degenerated or has been imperfectly regenerated Remember that all this distal end is in the same condition that you will not gain anything by cutting off successive pieces of it, and that you will not improve the cut section and find a better piece of nerve by cutting more of it off It is all equally degenerated or regenerated You have only to cut off enough to be sure that you have freed it from the scar tissue and then suture it to the uppermost part of the bulb In the next place, it is often a trouble to get the cut ends together because there may have been a good deal of separation. But generally much can be done by the position in which the limb is placed after such an operation. Thus in operations upon the median and ulnar nerves above the wrist a place where you often have to perform nerve suture, if you keep the wrist and the elbow flexed it is surprising how you can bridge across the gap and bring the separated nerve ends together Having done that and sewn up the wound the most important thing is to put the arm up in either a splint or in bandages so as to prevent any undue tension being thrown upon the nerve which has recently been joined Any strain might easily tear it and it is quite remarkable to see how in the course of two or three weeks after the nerve has been united the flexed wrist can be extended and the flexed elbow brought straight so that the cramped condition can be gradually got rid of and in a few weeks the hand and fore arm become relatively useful. You need not be afraid of putting a good deal of tension upon the nerve in bringing it together if you can relieve that tension by flexion of the wrist or elbow

As to the chief causes of failure, the first is that which I have mentioned before in regard to primary suture—sepsis If you do secondary suture and the wound suppurates you are very liable to have failure. But there is another cause of failure—namely the lapse of time, for the number of years that may have passed since the original injury may also have induced such changes in the motor fibres possibly in the spinal cord and certainly in the muscles that as far as motion is concerned you may have complete failure to record through no fault of your own.

Let me tell you a few cases briefly to indicate what amount of success you may expect after a given number of years have elapsed A student at this hospital when he first entered here had 10 years previously divided his ulnar nerve After he had been at the hospital two years he showed me his hand. It was an atrophied hand having the characteristic shape of ulnar paralysis. He wanted to know whether operation was likely to be of any use at the end of 12 years. I told him I did not anticipate that any success would attend operation as far as restoration of muscular power was concerned but that I could not speak with the same certainty with regard to sensation and that he might get some return of sensation. He was quite willing to have an operation and accordingly one was performed. The ends of the nerve were found and were sutured together There was no trouble, the wound healed well and a few weeks afterwards he began to have restoration of sensation. Ultimately he experienced a good deal of improvement though he never had perfect restoration of sensation to the part. As to motion he had no improvement at all the muscles remained just as atrophied and paralysed as ever Were he alive now—which I am sorry to say he is not—I am afraid we should have found that no further change in this direction had occurred. But for eight years after the operation was undertaken he had no improvement in the muscular power of the part and I think you may take it that he never would have had.

Now take a case in which the disability had lasted half that time An officer was injured in his elbow by a shell wound about 20 years ago in Egypt For six years he had ulnar paralysis and a good deal of pain at times, and it was the pain which induced him to have an operation undertaken with a distant hope of possible return of power in the hand An operation was undertaken, the ulnar nerve was found, and it was sutured without trouble, but as far as muscular power is concerned the operation remains a complete failure. He got a slight return of sensation, but even to the present day he has nothing like normal sensation in the part In that case also the wound healed by first intention without trouble So you see that after six years the same as after 12 years there was no attempt at the formation of new muscle, although there was in both of these patients a slight improvement in sensation

---

[1] Lecture I was published in The Lancet of July 19th p 123.

Now let us go to four years A man divided his median and ulnar nerves and four years afterwards an operation was undertaken for their suture He had a good deal of improvement in sensation and a very little return of muscular power He was satisfied himself that it was well worth while to have had the operation done, but I must say, looked at impartially, it could not be regarded as a success

Now another case. A man had his ulnar and median nerves sutured after two years and four months You see we are getting to nearer periods In the course of three years from that time he had some improvement of muscular power, but after that he had no material increase of that improvement So it took him a long time to mend his muscles at all and then he only mended them imperfectly

In another case in which a man divided his ulnar nerve operation was done one year and 11 months afterwards and the nerve was united without trouble At the end of one year and nine months more he had good voluntary power and his muscles reacted to electrical stimuli So you may say that that was a fairly successful case He had a good deal of restoration of muscular tissue and a good deal of return of sensation. That would be called a successful case, though, as I shall tell you directly, one has to consider the meaning of "success." The condition was not as good as before the injury, but it was much better than immediately before the operation Those then, are cases in which operation was undertaken at periods of time varying from one year and 11 months to 12 years and with the exception of one case, as far as motion was concerned, the operations were practically failures, though all the patients had some improvement in sensation

Next notice in the two following cases how irregular is the interval between the time of suture and the time of return of sensation and motion, and notice also that it has not any direct connexion with the length of time which has elapsed since the injury in cases where an operation has not been delayed for as much as two years and in many cases where an operation was performed early

An ulnar nerve was sutured four weeks after it had been divided. At the end of nine months more the muscles were still absolutely wasted and no return of muscular power was seen. Nine months later than that the patient had nearly complete recovery of his muscles and the faradic contractility returned soon afterwards In that case, where only four weeks had elapsed, it took more than a year to repair the muscles and about the same length of time to get good sensation In another case a man [illegible] had his musculo spiral nerve divided and it was not sutured till five weeks afterwards In six months he had a slight return of power and electrical reactions were present in one year You see, then, that it is difficult to speak positively about the amount of time which will elapse in a case of secondary suture before the good effects of your operation are evident. I think there are no known cases in which restoration of muscles has been at all perfect when operation has been delayed for as much as four years, that in most cases where an operation has been delayed for more than two years there is likely to be failure, and that in other cases where the operation has been done after a varying number of weeks or months but less than two years, it is at least about nine months or more before motion is restored, and it may be a year or two All this is very vague, you may say, but you can at all events be certain that your patients will have a considerable time to wait for a cure and you must tell them that although an operation is ultimately going to be successful there will be no improvement in power for at least six months

Now, what is the effect of operation on different nerves? Do nerves unite differently from each other? I have not the slightest doubt that they do, as far as the utility of the part is concerned If you were merely to consider the amount of sensation to the prick of a pencil or the amount of regenerated muscular tissue you might be inclined to say that there is not very much difference But when you compare the actual practical results of union of a median or ulnar nerve by either primary or secondary suture with the results of repair of the musculo spiral or peroneal nerves there is no doubt that, as far as restoring the part which is paralysed to its natural condition is concerned, it is much more difficult to restore a normal hand than it is to restore a normal forearm, upper arm, or leg I do not think that this conclusion presents any difficulty when you consider how very complex are the minute movements of the hand and how very important it is to have in the hand complete and accurate sensation A comparatively slight amount of sensation in the outer part of the leg or the outer part of the arm is all that anybody cares about, it is of no particular importance to feel specially well with the back of one's forearm, but it is of the utmost importance to feel well with the tips of the fingers Therefore restoration of sensation, imperfect though it be, which may be quite satisfactory for one part of the body may be very unsatisfactory for another part If you have to do with a man who has recently divided his ulnar or his median nerve you will say that this must be sewn together by primary suture, and you may properly say that in the course of time the man will, as far as his work is concerned, if he be, say, a navvy, be completely restored, that is to say, he will have a hand which is useful and he will have as much sensation in it as he will care to have for his work.

But take another case, one in which the ulnar or median nerve is divided in a man who is a cabinet-maker or a pianist or a violinist, conditions of work in which it is essential that sensation and minute movements in every part of the small muscles of the hand should be as complete and natural as possible What is the expectation in a case like that? It is that for this sort of fine work there will never be as good a hand as the man had before Therefore you may say in general terms that you do not expect to get a complete and satisfactory recovery, as far as muscular power is concerned, in a man whose hand has to be used for certain particular objects which require the perfection of movement in the small muscles I am sure that no man who played the violin, for example and divided one of the chief nerves of his left hand would ever be able to play again with the same facility, whatever operation was undertaken and however soon after injury it was performed. The same is true of the sense of touch It is one thing to restore a sufficient amount of sensation after having divided the musculo-spiral nerve and sutured it, for the parts which it supplies may be quite sufficiently innervated for the purposes of the patient, but if you divide the ulnar or median nerve in a man who has to use his hands in the ways which I have indicated he will consider that he has very imperfect sensation Thus you have to consider what you mean by "success" The amount of return of motion or of restoration of sensation which you may get in suture of one nerve may not spell success in another at all. A man came here with a divided ulnar nerve. He was a cabinet-maker and in his work he had to use fine small nails He could not afterwards feel these nails properly with the fingers, neither could he handle his work with the same dexterity, consequently he never earned the same wages afterwards Another man, a bootmaker, divided his median nerve In making the boots his custom was to fill his mouth with a considerable number of small nails which he pushed out with his tongue and then snatched them rapidly from his mouth and used them. He was never able to do that work again, because he could not properly feel the nails with his fingers He said he earned such small wages afterwards that although his nerve had united fairly well he had to give up his occupation So you see that although a man may have restoration of sensation and some restoration of power the question whether he has a really satisfactory return of the part to a useful condition depends very much upon what work he has to do, and you have to keep this in mind in telling people what sort of results they may expect from an operation which perhaps you have recommended

I now want to say something about the next difficulty which arises in secondary suture, and that is the difficulty which sometimes occurs in consequence of the nerve ends being so far separated that they cannot be approximated A man came to this hospital about 10 years ago who had a swelling in his median nerve just below the elbow It caused great pain in his hand and a considerable impairment in the movements of the hand muscles. I cut down upon it and found that there was a thickening of the nerve at this place and that there was what you may call a diffuse fibroma in the nerve I cut away as far as I could, what appeared to be the unhealthy tissue but it was not satisfactory because unlike most neuromata, there was no definite capsule or sheath to this tumour and there was not what you could call a definite tumour at all, it was rather a condition of fibrosis. However I did what I could to save the nerve and sewed the wound up. There was a little improvement, but in a few months the man came back as bad as he had been before, and the pain was so great that he could not do his work he could not handle anything and his hand was practically useless. Recognising that if I operated upon and cut away the diseased part of nerve I should be unable to bring the two divided ends together I had a rabbit killed in a neighbouring room to the operating theatre and at the time that I began the operation, and whilst I was dissecting out the median nerve from the scar tissue someone else opened up the spinal canal of the rabbit and took out the cord and then opened up its leg and took out the sciatic nerve. The sciatic nerve is a very small thing in the rabbit, and so I took both its sciatic nerve and its spinal cord and put them in together between the two ends of divided median nerve which were about three inches apart. The wound ran a perfectly aseptic course and there was no difficulty about its healing First of all the man lost all his pain as one would expect after cutting away the nerve which was the seat of pain. Next he had a pretty rapid restoration of sensation, so that within a few months he had a hand which was useful for his work. He had good tactile sensation and could perceive touch in all parts of the area supplied by the median nerve. His muscles had been much wasted before I finally operated upon him but afterwards they never became materially restored. They were slightly larger so that I thought sometimes I could detect slight movements of the muscles supplied by the median nerve, but I could never be quite sure that that man got restoration of muscular power

In some other cases of nerve grafting which have been recorded the results have been more satisfactory and sensation has returned and power has been restored I think that the chief drawback in the operation in which I used the rabbit's nerve was that I did not have a large enough animal killed. If I had to do the operation again I should take the nerve of say a dog or a sheep

Now supposing you are doing an operation and you come to a condition in which you divide or take away a piece of nerve and cannot get the ends together you will not, of course, have rabbits, sheep, or dogs waiting for you. What are you going to do then at the time of operation? You may do one of two things you may leave the ends wide apart and subsequently within the next two or three days, obtain the necessary animal kill it and take some of its nerve, or at the time you may split a part of the nerve and turn a piece of the split nerve down so as to bridge over the gap. I have never done that myself and I do not think that I should consider it very satisfactory, but it has been done and success is alleged to have followed the procedure

PARTIAL DIVISION

Partial division of a nerve is much less common than is complete division in civilian practice, but partial division of nerve by bullets in warfare is exceedingly common. As a rule, in cases where a nerve is evidently partially divided where some of the muscles supplied by it are paralysed and some are not, while some part of the skin supplied is anaesthetic and some is not, in those circumstances you may generally look forward to a restoration of the nerve without any operation being undertaken for the suture of it So partially divided nerves, as a rule, do not need to be operated upon, and if you can demonstrate to your satisfaction that perhaps the greater part of a nerve is not divided you may leave to nature and to the tissues themselves the healing of the divided fibres, remembering that if a nerve is partially divided the part which is not yet cut through holds the nerve ends together quite as well as any suture you could employ And in proportion as you think that nearly the whole of the nerve is divided so you will entertain the question of operation to repair the injury

CONTUSIONS

With regard to contusions it is remarkable to notice what complete paralysis may follow a mere contusion of nerve and how long the part may remain paralysed Some years ago a boy was admitted here having been run over and having injured his upper arm. When he came in he had complete paralysis of the parts supplied by the musculo spiral nerve. This paralysis persisted so that at the end of a month it was still complete. But it was noticeable that at the end of a month, although the motor paralysis was complete, there was some definite sensation in the skin supplied by this nerve and more sensation than there was soon after the injury A fortnight later there was no return of muscular power at all. In those circumstances the surgeon cut down upon the nerve to see whether it was cut in two by the contusion which possibly might have crushed it against the humerus and broken it into two halves. He found that it was perfectly normal—indeed as normal as a nerve could be. It showed no evidence of contusion and to the naked eye it looked perfectly healthy I have no doubt that its nerve tubules had been broken inside its sheath But they mended very quickly and well and in the course of another month that is to say two and half months altogether, the boy had perfect restoration of the muscles which were supplied by this nerve and which had been paralysed.

Let me tell you of a case in which a member of our profession had an injury to his median nerve in dislocating his forearm. The nerve must have been violently stretched and he immediately had complete paralysis of the part supplied by it. At the end of eight or nine months the parts were still as much paralysed as they had been soon after the accident and the application of electricity did not seem to improve matters materially But, on the other hand there was more sensation than there ought to have been in a part the nerve of which was completely divided and I therefore advised him not to be in a hurry but to be patient to go on with the massage and galvanism to keep the part warm and to use the hand. These cases, I told him sometimes took a long time to recover and you know that a nerve which is divided even if it is immediately sutured may take at least a year before muscular power is restored But in this patient there was one day a slight return of power in the long flexor of the thumb I hailed this as satisfactory and in the course of a few weeks from that time he began to get rapid restoration of power in the other muscles, though it was nearly a year from the time of the contusion before he had completely recovered. Now in both of these cases there was so much sensation retained that it was almost certain the nerve could not be completely cut across. And because of this one felt inclined to say that there was no necessity to do an operation for if the nerve tubules were only torn inside the sheath nothing could be gained by operation.

And now in conclusion let me try to sum up for you the chief facts as to treatment which I have put before you In the first place, nerves do mend in many respects as well as do other tissues of the body and, after a preliminary degeneration regenerative changes ensue in the peripheral end and are more complete in the sensory than in the motor fibres On the other hand you must not expect a too complete restoration of muscular power or of sensation especially in the case of nerves supplying the hand As far as the treatment of these wounds is concerned primary suture is the thing to aim at in all cases and when a primary suture has been undertaken and successfully carried out, and the wound has healed by first intention in those circumstances you may rest assured that the nerve will unite, and it will unite all the more quickly if you take care to keep the part in use, to keep it warm, to have it massaged and if necessary to have it galvanised It will surely unite in time and the more quickly if the patient be young Dissuade your patient, therefore from being in a hurry to have other operations done if primary suture has been satisfactorily performed and the wound has healed by first intention.

With regard to secondary suture, it ought to be undertaken in every case where in a punctured wound a nerve appears to have been either completely divided or so nearly divided as to make it probable that it has been materially injured and may perhaps be really divided In undertaking the operation of secondary suture do not encourage your patient too much if the interval between the injury and the secondary suture is a very long one My experience is that up to two years you may reasonably expect in the young a good restoration of sensation and muscular power. But after an interval of four years no one has ever yet recorded a case in which there has been complete restoration of motor power, although there have been cases of restoration of sensation. When you undertake these operations for secondary suture, therefore, remember that to some extent your prognosis is to be guarded, and in giving it you must be guided by the length of time which has elapsed and to some extent by the age of the patient and the particular nerve which is injured. You may give a much better prognosis, from the patient's point of view, in cases of wounds of nerves other than those which supply the small muscles of the hand with power and the fingers with sensation.

Five Clinical Lectures

ON

THE CAUSATION AND PREVENTION OF PHTHISIS.

BY BYROM BRAMWELL, M.D., F.R.C.P., F.R.S. EDIN.,
PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY, &C.

LECTURE IV.[1]

GENTLEMEN,—I propose to-day to direct your attention to the compulsory notification of phthisis. This and the great question raised by Koch—viz., whether bovine tuberculosis is communicable or not to man—are, in my opinion, the two most important questions connected with the prevention of phthisis and other forms of tuberculous disease. I am strongly of opinion that without compulsory notification it will be impossible to reduce the prevalence of phthisis and other forms of tuberculous disease to anything like the lowest possible attainable limit. If I am right in this opinion it is obvious that the compulsory notification of phthisis requires the most careful consideration. In this and the following lecture I propose to discuss the arguments for and against this measure in detail.

THE COMPULSORY NOTIFICATION OF PHTHISIS.

The advisability or non-advisability of adopting a compulsory system of notification for phthisis in this country has given rise recently to a considerable amount of discussion. There can, I suppose, be little doubt that the great majority of the profession are, at the present moment, opposed to the proposal. The Local Government Board is opposed to it. The late Sir Richard Thorne, the medical officer of the Local Government Board, and many of the leading members of the profession who have expressed an opinion on the subject have declared themselves strongly against it. Nevertheless, after most careful consideration, I have come to the conclusion that the advantages to be gained from a compulsory system of notification specially adapted for phthisis are far greater than the disadvantages and that such a system ought to be adopted.

I, however, make this statement entirely on the proviso that the object of the "crusade against phthisis" and other forms of tuberculous disease is not merely to reduce in some degree the prevalence of tuberculous diseases, but is to reduce the prevalence of these diseases to the greatest extent attainable by means of our present methods. If the object is merely to do what is possible to reduce the prevalence of phthisis in a way which is easy and agreeable, but which I venture to think would be very inadequate and very inefficient, then I admit that the compulsory notification of phthisis is not necessary and consequently not advisable. But if the object is to make a determined and vigorous effort to reduce the prevalence of the disease to the greatest extent attainable by our present methods then I maintain that some system of compulsory notification is essential, for without compulsory notification it is, I believe, impossible to take effective measures to prevent the tubercle bacillus being conveyed from one human being to another human being. I may add that unless measures are taken to stamp out bovine tuberculosis it will, in my opinion, be impossible (granting that bovine tuberculosis is communicable to man) to prevent tubercle being conveyed from the bovines (through milk) to man; in other words, it will be impossible to prevent the development in man of tabes mesenterica and the other forms of tuberculous disease which are due to the ingestion of tuberculous milk. Further, if it be granted that compulsory notification will materially aid us in our efforts to reduce the prevalence of phthisis and other forms of tuberculous disease to an extent which is impossible without some system of compulsory notification, then I am of opinion that the advantages to be gained from it are far greater than the disadvantages (large expenditure of money, worry and irritation, hardships on some individuals suffering from phthisis, &c.) which it would entail.

The benefit which would result to the human race from the complete eradication of phthisis is so enormous that it is difficult to estimate it. Phthisis is the most widely prevalent and fatal disease to which the human race is liable. In England and Wales alone considerably more than 40,000 deaths are registered every year from phthisis. Dr. A. Newsholme has estimated that between the ages of 15 and 55 one-fourth of the total number of deaths is due to phthisis. Dr. Hermann Biggs even goes so far as to state that more than one-half of the entire adult population at some time in life acquire the disease. In this country phthisis causes more deaths than all the other contagious and infectious diseases lumped together. Further, the great majority of the persons who die from phthisis are adults, whereas a large proportion of the patients who die from the contagious and infectious diseases scheduled, or included with the consent of the Local Government Board, under the Infectious Diseases (Notification) Act of 1889, are children. Again, as all of us know only too well, some of the victims of phthisis are amongst the best and brightest of the race—the very "salt of the earth"; our phthisical patients include some of the most useful and valuable lives in the community, or, if they had not been prematurely cut off, some who would have been most valued members of the community. Further, it must be remembered that if we could greatly reduce the prevalence of phthisis we would do a great deal to reduce the prevalence of other forms of tuberculous disease, for the sputum of phthisis is by far the most important medium through which the tubercle bacillus and its spores are conveyed from one human being to another human being. Keeping, then, these facts and statements in view let us consider the arguments which have been advanced against the compulsory notification of phthisis and the advantages which would result from it.

The first argument against the proposal is that the compulsory notification of phthisis would involve the divulging of a medical secret and that the public would not accept the proposal without protest and resistance. This objection is urged by the special commission appointed by the Académie de Médecine in Paris to report on the prophylaxis of tuberculosis. The commission recalls the fact that phthisis is not a disease that can be classed with the infectious diseases such as diphtheria and small-pox, but that, in the estimation of the public at least, it has a hereditary as well as an infectious aspect and as such it is a disease the incidence of which should not be noised about beyond the family circle.

This objection seems to me to be a sentimental rather than a practical one. If the compulsory notification of phthisis will materially aid us in our efforts to reduce the prevalence of phthisis and other forms of tuberculous disease this argument should, I think, be disregarded. It must be remembered that under a judiciously conducted system of compulsory notification, such as the New York system of notification for phthisis, no undue publicity would be given to the fact that a member of a particular family was affected with tubercle. Further, this argument lays far too much stress on the hereditary nature of phthisis. Heredity is merely a predisposing cause; it is, practically speaking, never the sole or the direct cause of phthisis. Consequently, if the public once thoroughly understand, as they ought to be made to understand, that in persons who inherit a hereditary predisposition to phthisis the development of the disease can (usually) be prevented provided that proper precautionary measures are carried out, and if it can further be shown that the compulsory notification of the disease would enable these precautionary measures to be much more effectually carried out than would otherwise be the case this objection falls to the ground. Again—and this is a weighty argument against this objection—the public in this country have already consented to the notification of the infectious and contagious diseases scheduled under the Infectious Diseases (Notification) Act of 1889—in other words they have already consented that the medical secret," if it should be so termed, should be divulged in the case of these diseases. Consequently if they (the public) can be convinced that compulsory notification is necessary and advisable for the prevention of phthisis they will not allow the argument that such notification involves the divulgence of a so-called medical secret" to stand in the way

---

[1] Lectures I., II., and III. were published in THE LANCET of July 5th (p. 6), 12th (p. 61) and 19th (p. 132), 1902, respectively.

The next argument which has been advanced against the compulsory notification of phthisis is that phthisis is a disease which was not included in the Infectious Diseases (Notification) Act of 1889 and that it was not intended that it should be included in that Act It is pointed out that the special characters on account of which the contagious and infectious diseases which are scheduled under that Act (or which have since with the consent of the Local Government Board, been included at the request of many local authorities under the Act) were made notifiable are not characteristic of phthisis These characters are (1) that they (the infectious and contagious diseases) are acute in their course and short in their duration (2) that their infective stage is short (3) that during their infective stage the physical condition of the patients who are suffering from them renders confinement necessary and that during the later stage of short convalescence when they are still infective, the patients are quite willing to continue in confinement (4) that during the course of the disease the patients are usually physically unfit to follow their employments, and (5) that, in the interest of the public (i.e. because of their infectiveness) it is highly undesirable that they (the patients) should, either during the course of the disease or the subsequent convalescent stage, follow their employments. Whereas in phthisis, not only is every one of these conditions absent, but, on the contrary precisely opposite conditions are present—viz., (1) the course of the disease is usually chronic and the duration often very prolonged (2) the infective stage is of very long duration and during a long term it may be of years, there is no reason, other than their ejecting infective sputa, which can be urged for placing phthisical patients under any control or restriction (3) the physical condition of phthisical patients does not, until the later stages of the disease, render their confinement to the house or to bed necessary and the patients would therefore not be willing to submit to such confinement, (4) until the later stages of the disease the patients are usually able to follow their employments and (5) for their own sakes, and for the sake of their wives and families (i.e. in order that they may earn their livelihood and be able to place themselves in the best position for curing or arresting the disease and be able to support those who are dependent on them) it is desirable that they should continue to follow their employments as long as possible.

These differences, with perhaps the exception of the last, are, of course, admitted. I say with perhaps the exception of the last since it is highly desirable, more especially so far as their own health is concerned, that in the early and curable stage of the disease phthisical patients should not continue to follow their employments, but should, for a time at least be placed in sanatoriums in order that they may be treated in the best possible way and in order that they may be instructed as to the measures and precautions which it is necessary to take both for the treatment of the disease and for the prevention of the extension of the disease to other members of the community and thoroughly trained as to the manner and methods of carrying out those precautions. The last is a most important point. If every patient suffering from phthisis could be placed for a few weeks in a well regulated sanatorium the benefit which would result, both to the patients themselves and to the community as a whole, would be incalculable. But the existence of these differences is surely not an argument against the compulsory notification of phthisis. It surely does not necessarily follow that because of these differences the compulsory notification of phthisis is not advisable. And it surely does not follow that because phthisis was not included under the Infectious Diseases (Notification) Act 1889 and because when that Act was passed it was not intended that it should be included under that Act, that with our increased knowledge of the curability and preventability of the disease and that *now* when we are all agreed as to the necessity for more vigorous preventive action it should not be included either under that Act, (1) provided that the action (the preventive measures) which would follow on such notification were restricted and modified in accordance with the special peculiarities of phthisis and in accordance with the differences which obtain between phthisis and the infectious and contagious diseases scheduled under that Act or (2) under a new Act based upon the special peculiarities of phthisis and (I suggest) entitled the Compulsory Notification Act for Phthisis The existence of these differences undoubtedly shows that phthisis should not be included under the Infectious Diseases (Notification) Act for the same reasons, or rather with the same objects, that the diseases under that Act were made notifiable but it does not prove that phthisis should not be made a notifiable disease for other reasons and with other objects. Further it, of course, naturally follows because of the existence of these differences that if phthisis were made a notifiable disease the action to be taken as the result of such notification must necessarily be very different from the action which it is necessary to take in the case of the infectious and contagious diseases scheduled under the Act of 1889

The whole question seems to me to resolve itself into this Will the compulsory notification of phthisis materially aid us in the prevention of phthisis and other forms of tuberculous disease? and if it will materially aid us towards this end—and in my opinion there is no doubt whatever that it would do so—are the disadvantages which would result from and the objections to a compulsory system of notification specially adapted to the peculiarities of phthisis sufficiently great and sufficiently well founded to overbalance the advantages and to negative its adoption? The advocates of the compulsory notification of phthisis have therefore to show (1) that the compulsory notification of phthisis would be beneficial (2) that it is possible to formulate a system of compulsory notification for phthisis which would both be effective and which would work well in practice and (3) that the advantages which would result from such a system of compulsory notification are greater than the disadvantages which would result from it.

The object of the compulsory notification of phthisis and the advantages to be gained from it—The object of the compulsory notification of phthisis is not, as in the case of the majority of the infectious and contagious diseases included under the Act of 1889 to restrict the liberty of the patients, to isolate them in their own homes, or to send them to hospital (though in a small proportion of cases in which the patients are a distinct source of danger to the community and especially to the healthy persons with whom they are in immediate contact, this is in my opinion, desirable and advisable)

The objects of the compulsory notification of phthisis are I take it, to locate the cases at the earliest possible stage of their development (i.e as soon as they come under medical observation) and to get full and accurate information as to the individual members of the community who are suffering from phthisis, the localities in which the cases occur the rooms and houses in which the patients dwell, the trades which they follow and the workshops, &c. in which they are employed. This information is necessary for the following purposes —

1. By its means any marked and obvious insanitary conditions in the rooms, houses, workshops, or localities in which patients suffering from phthisis live and work and in which cases of phthisis occur may (so far as this is practicable and so far as the removal of such insanitary defects falls within the sphere of action of the sanitary authority) be removed.

2. The phthisical patients and the persons with whom they are in close contact (their wives, families &c.) may by this means be informed and instructed as to (*a*) the general sanitary measures (ventilation cleanliness &c.) which should be employed in order to promote the cure of their disease, and as to (*b*) the special means (precautions) which should be employed in order to prevent the extension of the disease to the persons with whom they are in immediate contact (their wives, families &c.) and to the community at large. As Dr J Niven has pointed out When you know where the cases actually are you can make arrangements for a continued and persistent course of education (and I would add therapeutic and preventive measures) at those points at which they are certain to be useful. In this way the poorer[*] phthisical patients would be placed

---

[*] I say the poorer patients because in the case of well-to-do patients such instruction is unnecessary since it would certainly be given by the medical attendant and since such advice and instruction would in the great majority of cases at least, be at once acted upon

in a better position than they otherwise would be for promoting the cure of their disease and preventing the extension of the disease to others Consequently a system of compulsory notification would not only be of great importance as a means of preventing the extension of the disease to the unaffected members of the community but would be of great value to the patients themselves

3 The (poorer) patients affected with phthisis may, under this plan, be supplied (at the expense of the sanitary authority) with the necessary appliances for the destruction and disinfection of their sputa (sputum bottles and disinfectants)

4 The rooms and houses in which the disease develops and in which cases of phthisis recur (the phthisical centres) may be detected and, if necessary, disinfected. It is important to remember that the poorer class of patients affected with phthisis are very migratory and that without some system of compulsory notification it is in many cases quite impossible to ascertain the rooms, houses, and places in which the disease, as it undoubtedly is in some instances, is contracted I do not say that a system of compulsory notification would enable us to locate the place of origin of the disease in any but a certain (and possibly only a comparatively small) proportion of cases, but it would certainly enable us to locate the phthisical centre in which the disease was contracted in some cases and such information would be of very great value for the purpose of prevention Further, it is absolutely impossible to obtain this information in any other way A system of voluntary notification, which has been advocated by many leading authorities, would, in my opinion, be, comparatively speaking, of very little use. Voluntary notification, which is, after all, merely a makeshift and a compromise, would, in my opinion, be most inadequate and unsatisfactory As compared with compulsory notification it seems to me to be a mere trifling with the subject

5 The sanitary authority may, on the death or removal of phthisical patients (but only in those cases in which the assistance of the sanitary authority is demanded by the medical man in attendance or in which independently of such demand there is good reason to suppose that such rooms are definite phthisical centres), take the necessary measures (either at the cost of the ratepayers or of the owners[3] of the property) to purify, disinfect, renovate, and put into a good sanitary condition rooms and houses which are contaminated with the tubercle bacilli. It seems to me (1) that it is only by means of some system of compulsory notification that the phthisical patients and phthisical centres can be located, at all events in anything like a complete way, and (2) that unless full and accurate information is obtained on these points that it is impossible to carry out in anything like a thorough and satisfactory manner many of the preventive measures which are essential in order to protect efficiently the healthy members of the community from the disease, and in order to endeavour to reduce the prevalence of phthisis to the lowest attainable limit.

Up to this point there will probably be no great difference of opinion amongst those who, like myself, are in favour of a compulsory, as opposed to a voluntary, system of notification for phthisis As to the advisability of the next two headings, which involve giving to the sanitary authority compulsory powers to *insist* that the necessary preventive measures are satisfactorily carried out and to remove dangerous cases of the disease to hospital, there can, I think, theoretically, be no doubt for such measures would be of immense value if they could be carried out, and are, theoretically at least, the logical sequences of any system of compulsory notification

6 By the system proposed the sanitary authority and the medical officer of health may, when their assistance and intervention are demanded by the medical man in attendance,[4] see, so far as this is practicable and so far as their authority will allow, that these preventive measures (destruction or disinfection of phthisical sputa, attention to free ventilation, cleanliness the non accumulation of phthisical dust, &c) are carried out

7 The sanitary authority may remove to hospital those phthisical patients who because of either (*a*) the insanitary nature of their surroundings (overcrowding, &c.) and the advanced stage of their disease, are unable to carry out the necessary precautionary measures, or (*b*) because of the insanitary nature of their surroundings and their refusal to carry out the necessary preventive measures, are a distinct source of danger to the persons with whom they are in immediate contact and to the community at large

That these measures would, if they could be effectively carried out, without imposing undue hardships and burdens upon the phthisical patients themselves and upon the healthy members of the community, be of the greatest value in preventing the extension of the disease, everyone will, I suppose, allow The only debateable questions are whether it is the business of the sanitary authorities to undertake all of the duties indicated above for the prevention of phthisis, whether they have the power to do so, whether it is advisable that they should do so, and whether the advantages to be gained by a judicious system of compulsory notification specially adapted to phthisis would be greater than the disadvantages In short, the question seems to me to resolve itself into this Is it possible to devise a system of compulsory notification for phthisis which (1) would be effective and which would work well in practice, which (2) would not unduly restrict the liberty of the public and of the patients affected with phthisis, which (3) would not be attended with intolerable worry and annoyance to the community, which (4) would not place unjust and unjustifiable hardships upon phthisical patients, which (5) would not do any positive harm, for it is argued that the compulsory notification of the disease would prevent patients suffering from early phthisis placing themselves under medical treatment and so would be harmful, and which (6) would be worth the heavy expenditure which it would necessarily involve?

Another argument which has been advanced against the compulsory notification of phthisis is that phthisis differs from the infectious and contagious diseases scheduled under the Act of 1889 in the important fact that the infection, instead of being, as in the case of those diseases, almost entirely beyond the control of the affected persons, is all but limited to the sputa, the disposal of which can easily be controlled by the patient. It is consequently suggested that there is no need for the compulsory notification of phthisis, or, at all events, that the compulsory notification of phthisis is less necessary and less advisable than the compulsory notification of the contagious and infectious diseases scheduled under the Act of 1889

But surely the very contrary is the case. Surely the facts (1) that the infection of phthisis is, except in a comparatively small number of cases, limited to the sputa[5] and (2) that this source of infection can in most cases (provided that the patient will carry out the necessary measures for the destruction or disinfection of the sputa) be easily controlled constitute one of the strongest arguments which can be advanced in favour of the compulsory notification of the disease I desire to emphasise as strongly as words can do the importance of this point. In the case of most of the infectious and contagious diseases included under the Act of 1889 the manner in which the poison is given off from the bodies of affected persons and distributed makes it infinitely more difficult to destroy the poison and to prevent the infection being conveyed to healthy persons who are brought into contact with the patient than it is to destroy the poison of phthisis and to prevent the poison of phthisis (the tubercle bacillus and its spores) being conveyed to healthy persons And, further, the susceptibility of the great majority of healthy persons who are not immune (i e., protected by a previous attack of the disease or by vaccination, as in the case of small pox) to the virus of every one of the diseases scheduled under the Act of 1889 is much greater than the susceptibility of the great majority of healthy persons to the poison of phthisis (the tubercle bacillus) In other words, provided that one can locate a case of phthisis, it is a simple and easy matter, if the necessary precautions and preventive measures are carried out (and these precautions and preventive measures are simple and easy to carry out), effectively to prevent the further extension of the disease, but in the case of most of the infectious and contagious diseases scheduled under the Act of 1889 it is

---

[3] In New York the owners of the property are obliged within a certain time after receiving notice from the sanitary authority to renovate the contaminated property if called upon by the sanitary authority to do so

[4] The reason for this important qualification will be explained later

[5] That is those cases in which there is tuberculous disease of the intestine and diarrhœa tuberculous disease of the urinary tract with the presence of tubercle bacilli in the urine and tuberculous disease of bones and joints with discharges containing the tubercle bacillus

(unless the patient is carefully isolated during the whole period of infection) a very difficult or impossible matter to prevent the further extension of the disease. In short, phthisis is a far more preventable disease than any of the diseases scheduled under the Act of 1889 This fact—the fact that the poison of phthisis can be so easily dealt with and controlled—is, I maintain, a very strong argument in favour of the compulsory notification of the disease.

Another argument against the compulsory notification of phthisis is that the disease is difficult to diagnose in its early stages and that many cases do not present themselves for diagnosis until the disease has been in existence for some time, consequently that a compulsory system of notification would be too late to be effective, for it would not enable us to prevent the distribution of the poison in the early and unrecognised stage of such cases. This argument undoubtedly shows that it would not be possible by means of compulsory notification *alone* completely to eradicate and to stamp out the disease. But compulsory notification, in conjunction with the other measures which I have advocated, would nevertheless I maintain, enable us to diminish the prevalence of the disease in a degree which it is impossible to do without compulsory notification.

Whether phthisis could ever be completely eradicated by any means which we at present have at our disposal may well be doubted, but that its prevalence can be enormously reduced if effective measures of prevention are employed is I think, certain and amongst these means I place in the forefront the compulsory notification of the disease. Further if such diseases as measles and whooping-cough should be notified (and although they were not originally included in the Act of 1889 they have, with the consent of the Local Government Board, been included by the request of some local sanitary authorities under that Act) surely phthisis should be notified In the case of measles and whooping cough the poison is given off from the bodies of affected persons in the earliest stages of the disease and susceptible persons with whom the patients are in contact are usually infected before the nature of the disease is suspected or recognised In the case of these diseases the only effective means by which the poison can be controlled even after the disease is recognised is strict isolation Further persons who are not immune in consequence of having already suffered from the disease are highly susceptible to the poison of these diseases and almost always contract the disease when exposed to infection. But in the case of phthisis, although the poison may be given off before the patient comes under observation and before the nature of the disease is recognised, the amount of the poison which is given off in this way is comparatively to the amount which is given off in the later stages of the disease—i.e. after it is diagnosed and recognised—very small. Further the virulence of the poison, or rather perhaps I should say the susceptibility of healthy persons to be affected by the poison (i.e. to contract the disease) is comparatively speaking slight. Again and this is the most important point, after the nature of the disease (phthisis) has been recognised the infection can be readily and easily controlled The compulsory notification of such diseases as measles and whooping cough is, consequently in comparison with the compulsory notification of phthisis of infinitesimal value for the purpose of prophylaxis Hence if measles and whooping cough should be notified (but from this statement it must not be supposed that I advocate their notification) *a fortiori* other objections being for the moment left out of account, phthisis should be notified. Further as Dr Newsholme has pointed out —

> The last Factory and Workshops Act contains a clause securing the compulsory notification of anthrax phosphorus and arsenical poisoning and of a chronic disease like lead-poisoning occurring in connexion with industries. Each of these has an annual number of victim that could almost be counted on the fingers, while thousands of the artisans of this country annually fall victims to phthisis acquired in connexion with their special work. But lead poisoning must be notified phthisis is ignored The non-communicable disease must be notified the communicable disease is left to carry out its maleficent work

The next objection to the compulsory notification of phthisis is the difficulty of ascertaining how far practical measures for the prevention of the disease can be supplied as the result of such notification It is pointed out that the advocates of compulsory notification are not agreed as to the action which should be taken as the result of such notification. Some would limit this action to the diffusion by means of leaflets, &c. of knowledge as to the precautionary measures (destruction of sputum &c.), which it is advisable that phthisical patients and the persons with whom they live should take in order to prevent the extension of the disease. Others would extend this action to the periodical inspection by special officers appointed by the local authority of the houses workshops, &c. in which phthisical patients live or to the disinfection of the rooms and houses in which phthisical patients have died. Others, again advocate the erection by the sanitary authority of sanatoriums at the cost of the rates of hospitals for the prevention of infection, and so on.

The measures (in addition to the general sanitary measures which everyone is agreed that it is the duty of the sanitary authorities to carry out) which in my opinion, it is the duty of the sanitary authorities to take in order to protect the healthy public from phthisis, if the object of the crusade against phthisis" is to reduce the prevalence of the disease to the lowest attainable point, include (1) the compulsory notification of the disease, (2) the provision at the expense of the rates of laboratories for the testing of sputum and other suspected discharges, and of milk meat, &c., supposed to be tuberculous, and reporting thereon (3) the removal (so far as it falls within the sphere of the sanitary authority to remove them) of any insanitary conditions which are harmful to patients affected with phthisis or are likely to conduce to the propagation of the disease to those healthy persons with whom they live and work, (4) the diffusion (by leaflets &c.) of information regarding the nature of the disease its modes of propagation and the precautions which should be taken by the phthisical patient and by those with whom he is in close contact in order to prevent the extension of the disease (5) the provision at the expense of the rates, of the necessary appliances (spittoons and disinfectants) for the destruction and disinfection of the sputa (6) the periodical inspection by competent officers paid for and provided by the rates—but only in those cases in which such inspection is demanded—i.e. considered advisable and necessary by the medical man in attendance—of phthisical patients, their homes and workshops with the object of seeing so far as this is practicable and so far as such measures fall within the sphere of the sanitary authority that the necessary preventive measures are carried out (7) the removal to a hospital to be provided and maintained by the sanitary authority or by the sanitary authority and by the Poor law authorities conjointly of those cases of phthisis which are a distinct source of danger to the persons with whom they live and to the community, and (8) after the death or removal of phthisical patients the purifying renovating and disinfecting (either at their own cost or the cost of the owners) of phthisical centres—i.e. of rooms and houses which are contaminated with the tubercle bacillus. Everyone will I suppose, allow that if such measures could be effectively and systematically carried out for a sufficiently long period of time that they would be of the greatest value in the prevention of phthisis and other forms of tuberculous disease. Further as has been already stated, I maintain that it is impossible, except by a compulsory system of notification to obtain the information with regard to the location of phthisical patients which is absolutely essential in order that these measures may be carried out in anything like an effective and systematic way

The next objection is a financial one. Such a system as that indicated above would involve a very large expenditure of money It would necessitate the payment of notification fees to medical men the payment of a staff of skilled inspectors and of a certain number of clerks the erection and upkeep of laboratories for the examination of phthisical sputum &c and the erection and upkeep of hospitals for the reception of the dangerous cases of phthisis. But although the financial cost of such a system would for some years be very great, it must be remembered that it would be a rapidly decreasing expenditure for as phthisis became—as I believe it rapidly would do if these measures were effectively carried out—less and less prevalent the expenditure would rapidly decrease Nevertheless the very large expenditure which would for some years be required is a weighty objection But against this great expenditure the benefit to be derived from such a system of compulsory notification of phthisis have to be placed If we could reduce the mortality of phthisis from 50 000 per annum in this country to say 10 000 per annum—and I maintain that with the aid of such a system of compulsory notification and the preventive measures based thereon which I have [illegible] the course of time [illegible] late bovine tubercu[illegible] [illegible] cation we cannot possibly hope to attain this end—the result would, in my opinion, abundantly justify the expenditure. In short, the financial argument *per se*, in my opinion, is altogether insufficient to negative the proposal. It must, of course, be remembered that compulsory notification does not necessarily entail subsequent inspection, the provision of laboratories for the testing of sputum, &c., and the provision of hospitals for the reception of the dangerous cases, and that if these measures were not included in the scheme the cost of compulsory notification would be enormously reduced But, in my opinion, the compulsory notification of phthisis *per se* (without periodical inspection in those cases in which such inspection was demanded by the medical man in attendance and the provision of laboratories and of hospitals for dangerous cases), though it would undoubtedly be of considerable use—for it would afford much valuable information as to the location of cases of phthisis by means of which the sanitary authority would be able to focus their general sanitary efforts more powerfully than they can at present do upon the points where such efforts are most needed—would be of little use in comparison with the complete scheme which I have sketched out.

ON PUERPERAL APHASIA, WITH AN ANALYSIS OF 18 CASES

By M. A. McINTYRE SINCLAIR, M.D Glasg, D P H Cantab

"PUERPERAL aphasia" is a term which has not yet, so far as I know, found its way into our medical nomenclature, although the classical paper of Poupon[1] on the subject has given it a distinctive significance in continental records. In the following discussion I wish to follow the classification which that author has laid down and to include under the term not only cases of loss of speech occurring during the strictly puerperal period but also cases occurring during the later months of pregnancy I follow this arrangement not merely because it forms a convenient grouping of cases for discussion, but because underlying it there is a pathological factor which I believe must be taken into account in all cases of aphasia occurring at this time. The factor I refer to is the altered condition of the maternal blood for a certain period before and after delivery and the greater tendency of the blood at this time to undergo clotting within the vessels. I wish at the outset of my paper to lay stress on this point, since it has apparently escaped altogether the notice of Poupon, indeed, in his discussion of the etiology of the affection this author deliberately discards the occurrence of cerebral thrombosis as a factor in the induction of puerperal aphasia I shall, however, take the opportunity of returning to this point at some length later in my paper

My attention was first drawn to the subject by the occurrence of a case of typical aphemia in my practice some years ago, the loss of speech taking place during the later months of pregnancy in a woman apparently free from cardiac or other ailment. Full notes were taken of the condition at the time, but I purposely omit all particulars which do not bear directly on the subject in hand

CASE 1.—A married woman, aged 27 years, with no evidence of cardiac or vascular disease and with a good family history, was suddenly affected with total loss of speech in the latter half of the seventh month of her fourth pregnancy She retired to bed in her usual health on the evening of Sept 16th, 1896, on the following morning, after sudden emotional excitement, she lost her speech for a period of about an hour's duration, later in the same forenoon she had a second very transitory loss of speech, this time more gradual in its onset but also passing off in less than an hour's time. At 3 P M of the same day embarrassment of speech again manifested itself, the patient was observed to speak more slowly and with increasing difficulty until 9 P M. when the attack culminated in total loss of speech for the thir time. She remained speechless on awaking next mornin and when I saw her later, in the forenoon I found a conditio of complete motor aphasia without agraphia (aphemia). Sh could not articulate the simplest words, such as "yes" c "no," nor could she repeat them after hearing them pr nounced Yet it was quite evident that she understoo everything that was said to her, and she was able to mak reply either in pantomimic or in written speech. There wa no other paralysis on this date although specially looked fo but on the following day (the 19th) I found distinct pares with loss of sensation in the right upper extremity, most c all in the right thumb and forefinger, while the patient als complained of a numbness at the right angle of the mouth On this day also the patient had an attack of phlebitis an thrombosis of the smaller veins above the right ankle. Speec returned slowly but surely from about the third day after th attack. At first she could only use the simplest words i common use, and when she could not make herself unde stood by words, or by words interspersed with pantomim she resorted to the use of a slate and pencil. In abo three weeks she was sufficiently recovered to piec together phrases and small sentences She read alou some of Scott's poetry every day, and in this way graduall mastered most of the difficulties of pronunciation. O Nov 25th (10 weeks after the attack) she was confined c a healthy full time child Labour was natural and eas She still spoke in a slow, hesitating style, and if flurried sh stumbled occasionally in her speech, but it could not be sa that any relapse in her condition followed delivery Wit rest and care she progressively improved, and although sh could not speak with her former freedom of utterance fo several months she ultimately made a perfect recover Coincidently with the improvement in speech the numbne and paresis of the right upper extremity also gradually di appeared. There were no disorders of lactation and the was no evidence of syphilis in the personal or family histor I have already noted the absence of cardiac disease an there was no history of rheumatism Physical examinatio elicited nothing apart from the above history. The patie was a person of unusually calm disposition and the eleme of hysteria could safely be excluded. As to the after histor of the case, two years after the above attack the patien again became pregnant. Fearing a recurrence of the aphas for reasons to be afterwards stated, it was considered ad visable to terminate the pregnancy at the earliest possibl moment, and abortion was purposely induced at two and half months. There has been no recurrence of the aphasi and when last I heard of the patient about a year ago sh was in the enjoyment of perfect health.

The only other contributions to the subject of puerper aphasia which I have been able to find are those of Bateman Leith Napier, and Finlayson[3] in our own country, and thos of Lewandowski[4] and Poupon in continental records. It i of course possible that I have overlooked some of the litera ture on the subject, but at any rate my search has convince me of the rarity of the disease Kussmaul in his great wor on defects of speech does not mention an instance, nor doe Sireday in an analysis of 8000 consecutive cases of labou At the same time I am bound to say that Bateman in hi *résumé* has hardly done sufficient justice to his own country men, and he has overlooked at least a couple of most inte resting cases which I have been fortunate enough to fin reported by Finlayson. It is only doing Finlayson tard justice to say that his two cases were not only among th first recorded, but that they also illustrate some of the mos salient features of the affection—amongst others, the te dency to recurrence of the aphasia in a subsequent preg nancy In the accompanying list of 18 cases which I hav accumulated in the course of my reading I have endeavoure to set forth the main features of each so far as the literatu of the subject has been available to me, in some cases it is t be regretted that the details are somewhat bare. Among th first 12 which are taken from various authors by Poupo several are described in such ambiguous terms (*"troubles d la parole"*) that it is doubtful whether or not they are case of true aphasia. However, I have decided to retain them a here since they have already in a way the impress o Poupon's authority and their inclusion will add completenes

TABLE GIVING ANALYSIS OF 18 CASES OF PUERPERAL APHASIA.

No of case	Author	History of attack	Remarks
1	Poupon.	The patient was a woman aged 24 years Second confinement; the labour was easy; on the second day after delivery there was loss of speech with right hemiplegia; word-blindness but no word-deafness Gradual recovery	The lesion was attributed to embolism of the left Sylvian artery There were mitral disease and a history of rheumatism
2	Burrows.	Six weeks after confinement there were embarrassed speech and impairment of memory Death.	Embolism of the left middle cerebral was found post mortem, also mitral and aortic disease.
3	Ireland	Seven days after confinement there was loss of speech albuminuria Sudden death.	Softening of the left hemisphere was found post mortem due to vascular lesion.
4	Charpentier	There were left hemiplegia and loss of speech with transitory deafness following accouchement at term slight albuminuria. Recovery in 44 days.	Attributed by Charpentier to septicæmic accidents and by Poupon to vascular lesion.
5	Churchill.	Eight days after accouchement there was paresis of the face and the arm; loss of speech Partial recovery of speech after two months.	Attributed by Churchill to albuminuria and by Poupon to vascular lesion
6	Darcy	The patient was a woman, aged 27 years Two days before confinement there were right hemiplegia and loss of speech; albuminuria Partial return of speech two days later and disappearance of the hemiplegia eight days later	Attributed to cerebral congestion
7	Cuffer	The patient was a woman aged [illegible]8 years Some days after confinement and without apparent cause left hemiplegia and aphasia supervened with coincident lacteal derangements. Rapid recovery	Vascular lesion following anæmia (?) The patient was left handed."
8	Mattei	The patient was a woman, aged 34 years. There was abortion with considerable hæmorrhage at the fifth month; three days later there were numbness of the left leg and inability to make herself understood, the attack lasting one hour; two days after this another aphasic attack occurred which disappeared on the removal of a large fæcal mass from the lower bowel	Attributed by Mattei to anæmia or to a reflex disturbance and by Legroux to uræmia.
9	Leven	The patient was a woman, aged 18½ years In the seventh month of pregnancy following emotion there were sudden loss of consciousness and paralysis of the right side first of the leg and later of the arm; three days later there was loss of sensation; again three days later there was loss of speech. Slight improvement occurred after the confinement. During the second pregnancy there was loss of speech lasting for 15 days. Paralysis after delivery	Attributed by Leven to hysteria. Note the recurrence of aphasia in the subsequent pregnancy
10	Leith Napier	There was loss of speech 17 days after confinement (the delivery was natural and easy); cramping pains in calf of leg; the temperature was normal; three days later partial paralysis and again two days later complete hemiplegia. Progressive recovery	Attributed by Leith Napier to cerebral embolism and by Poupon to nervous origin; no cardiac disease.
11	Gignoux	In the sixth month of the first pregnancy there was sudden aphasia lasting half an hour and then passing off completely; natural confinement at term In the eighth month of the second pregnancy an attack of aphasia occurred lasting for 20 minutes and passing off as suddenly as it appeared	Attributed by Poupon to nervous" origin Note the recurrence of aphasia in the subsequent pregnancy
12	Gignoux	The patient was a woman aged 24 years. At the second pregnancy (at term) forceps were applied on account of uterine inertia; on the second day after delivery there was turgescence of the breasts but no fever on the same evening sudden loss of speech occurred without unconsciousness Gradual improvement next day and after two and a half months complete restoration of speech.	Attributed to nervous origin by Gignoux Poupon suggests anæmia as a possible alternative cause.
13	Finlayson.	The patient was a woman, aged 32 years. Second confinement, followed 10 days after delivery by complete aphasia and slight paresis on the right side. Partial recovery from aphasia at the age of 35 years. The third confinement was followed by complete loss of speech and numbness and paresis of right hand but no agraphia. Aphasia was persistent.	There was no cardiac lesion Note the recurrence of aphasia in the subsequent pregnancy
14	Finlayson	The patient was a woman, aged 37 years. Ninth confinement (natural labour) followed three weeks later by aphasia and right hemiplegia. The aphasia passed off in a few days and the hemiplegia in three weeks At 39 years of age the patient was confined for the tenth time (labour tedious) followed suddenly on the twentieth day by complete aphasia and marked hemiplegia of the right side. Aphasia persistent and ensuing rigidity of paralysed limbs.	There was no cardiac lesion Note the recurrence of aphasia in the subsequent pregnancy
15	Lewandowski	The confinement was followed on tenth day after delivery by sudden loss of speech without unconsciousness Next day she could say No; and there was gradual recovery of both speech and writing after three days	The attack was transitory
16	Lewandowski.	The confinement (labour difficult) was followed on the ninth day by rigor headache, pyrexia, and slight tetanic convulsions; about the thirteenth day there was loss of speech but the patient was still conscious and was able to move her limbs and tongue freely Death on the seventeenth day	The necropsy revealed inflammation of the brain and the membranes; in the left anterior convolution a partly decomposed focus of the size of a walnut was found also several purulent foci in the lungs and suppuration of the veins of the ovario-uterine plexus.
17	Bateman	The patient was a woman aged 22 years At the seventh month of her first pregnancy the patient had some obscure symptoms with embarrassment of speech lasting about a month Early in the seventh month of her succeeding (second) pregnancy there was paresis of the right arm and the right leg; at the beginning of the ninth month embarrassment of speech was noticed culminating in complete aphasia six days after delivery which was natural and easy; there was no loss of consciousness on the eighth day after delivery there was right hemiplegia. Death from exhaustion occurred six weeks after the confinement.	There was neither cardiac disease nor history of rheumatic fever Note the recurrence of aphasia in the subsequent pregnancy
18	Sinclair	The patient was a woman, aged 27 years. In the seventh month of the fourth pregnancy there was onset of total aphasia without agraphia two days later there was slight paresis of the right arm; phlebitis and thrombosis of veins in the right leg There were no lacteal derangements. Natural delivery at term Progressive improvement occurred from the third day and ultimately complete recovery	There was no cardiac disease or history of rheumatic fever Abortion was induced in subsequent pregnancy and there was no recurrence of the aphasia.

to my paper The remaining six cases are narrated by Finlayson (two), by Bateman, by Lewandowski (two), and by myself I think these 18 instances will be found to afford us sufficient material for the survey of what appears to be a somewhat neglected group of cases

An examination of the accompanying list of tabulated cases will at once reveal the fact that puerperal aphasia may be due to several causes Poupon considers these under two broad classes (1) those due to nervous origin, and (2) those due to vascular origin Let me say at once that I admit the occurrence of cases due to a nervous dyscrasia such as hysteria or reflex disturbance. It must be borne in mind that during pregnancy the whole mental attitude of a woman often undergoes profound change, she may become fretful or capricious, and in many cases has less control of the emotional faculties. The occurrence of a puerperal aphasia of neurotic origin, therefore, would not be surprising when we remember that a similar loss of speech may occur apart from pregnancy altogether At the same time I cannot help thinking that Poupon lays too much stress on this factor and there are several cases in his list which he attributes to nervous origin which might, in my opinion, be more fairly accounted for by vascular lesion. Leith Napier's is a case in point. That author attributed the aphasia to cerebral embolism Poupon disagrees with him, and in the absence of any reported cardiac disease would attribute the case to a neurotic element. It is, however, not my purpose to dwell long on this group of cases, about whose actual occurrence there can after all be little difference of opinion, but before considering the vascular group, which presents many interesting features, I would interpolate the fact that an occasional case of aphasia may follow delivery where pyogenic infection has unfortunately taken place Poupon was not aware of such an occurrence and it is interesting to read his disquisition on "*les petits microbes*" in the light of our later knowledge At any rate, the case which I have quoted from Lewandowski disposes effectually of this point, and we may say that the occurrence of a definite aphasia in a pyæmic case following delivery should at once suggest the existence of a fresh focus of the disease in the left cerebral hemisphere Such an occurrence must, of course, be exceedingly rare

I shall now consider Poupon's second group—i e, those due to vascular lesion These have afforded me much interest in view of the fact that more recent cases materially modify the conclusions which that author has laid down Passing over those transitory cases which possibly owe their origin to cerebral "congestive attacks" Poupon goes on to consider the relation of the loss of speech to cerebral thrombosis, to embolism, and to hæmorrhage It has, of course, to be remembered that the child bearing woman is at an age when the blood vessels are usually intact and are as yet unaffected by the degenerative changes which make their appearance in the decades following the climacteric. The possibility of cerebral hæmorrhage might therefore be considered remote, unless, perhaps, in the presence of albuminuric complications Poupon has no hesitation in crediting cerebral embolism as the main factor in the causation of puerperal aphasia and he is inclined to exclude both hæmorrhage and thrombosis from his calculation. It is quite clear that in the case of women suffering from mitral or aortic disease a vegetation might easily during the stress of labour become either wholly or partially detached and so lead sooner or later to the occurrence of cerebral embolism In the event of the left Sylvian artery intercepting the plug we should find aphasia accompanied by more or less hemiplegia. Such instances have doubtless often occurred and the sequence of events is so clear that I need not labour the point

But what are we to say regarding a fair residuum of puerperal aphasias in which the blood-vessels show no signs of degeneration and in which there is no cardiac disease, no albuminuria, and no suspicion of the neurotic habit? In these cases I believe the key to the situation lies in the composition of the blood itself and the greater tendency which puerperal women have to the formation of clots within the vessels I am bound to enter into this point at some detail because Poupon, who alone, so far as I know, has hitherto attempted to treat the subject systematically, is inclined to exclude altogether the occurrence of cerebral thrombosis as a factor in the causation of puerperal aphasia. "*Ce n est qu une hypothèse jusqu'ici*" It will be my object to show that its occurrence is no hypothesis, but that on *à priori* grounds as well as from clinical observation we are fully justified in saying that cerebral thrombosis explains a fair proportion of cases of aphasia occurring both before and after delivery In the consideration of this question let me first of all point out one important fact, and that is the time of occurrence of the aphasia A careful scrutiny of the cases in the accompanying table will reveal the fact that with one exception the aphasia in all of them developed either during the four later months of pregnancy or during the period immediately following delivery Now this period exactly corresponds with that in which numerous analyses of the blood have shown it to be most profoundly altered The researches of Andral and Gavarret have been epitomised as follows and I am not aware that these conclusions have been disputed by later writers on the subject. "In the earlier months of pregnancy the blood deviates but little from the normal standard In the later months, however, the blood is characterised by a remarkable diminution in the number of red corpuscles and a considerable increase in fibrin, while the proportion of albumen is somewhat diminished It would appear, further, that in some cases at least the proportion of white corpuscles is increased An estimate has been made by the same observers according to which they assume that, if we suppose the average number of red corpuscles in the blood of healthy women who are not pregnant to be represented by the number 125, the average in women towards the end of pregnancy is probably not more than 116 If, in like manner, we take 300 as representing the physiological average of the fibrin, the proportion of that constituent up to about the sixth month may be set down at 250, while from this period onwards during the last three months of gestation it steadily increases in quantity and reaches as high in extreme cases as 480" "These phenomena," adds Leishman,[5] "are further interesting in connexion with the occurrence of thrombosis in the pregnant state" "The increase of fibrin and extractive matter in the maternal blood goes far," adds Playfair,[6] "to explain the frequency of certain thrombotic affections observed in connexion with pregnancy and delivery" We may fairly conclude, I think, that on *a priori* grounds the occurrence of a puerperal aphasia due to cerebral thrombosis ought to be regarded as no unlikely contingency

The results of clinical observation are no less certain A careful examination of the above list of cases will indicate that many of them presented symptoms undoubtedly referable to a thrombotic lesion Bateman, in discussing his case (Case 17), says "From the comparative rarity of the association of loss of speech with the puerperal state I hesitate to venture upon any decided opinion as to the pathology of the above case The symptoms could scarcely be due to any merely transient cause, for they had existed in a modified form for three months before parturition and became intensified a few days before labour, the absence of any cardiac lesion and the gradual development of the nervous symptoms would rather point to cerebral thrombosis than to embolism." Bastian[7] in his work on Aphasia refers shortly to Bateman s case and throws the weight of his authority on the side of a thrombotic element in some of the cases under consideration Again, Finlayson takes up quite a decided position on the matter In a discussion of his own two cases he says "In neither could we detect evidence of any valvular disease of the heart, neither of them had a history of rheumatic fever, the age of the first woman was 35, and of the second 39, we may, therefore, fairly suppose that the mischief was due to the tendency which puerperal women have to the formation of clots in their vessels and so to the subsequent occurrence of embolism in various forms" Finlayson, therefore, lays stress on the thrombotic origin of the condition, although his remarks leave it to be inferred that the thrombus need not primarily form at the seat of ultimate lesion The questions of cerebral embolism and cerebral thrombosis are closely correlated in many instances and we may have a small embolism forming the nucleus for an extension by thrombosis Leith Napier attributed his case to embolism, in the absence of any cardiac disease I am inclined to question whether it was not due to thrombosis pure and simple In any case the symptoms clearly indicate that the condition was partially, if not altogether, due to the thrombotic element The patient, 17 days after delivery suddenly lost her speech this was followed only three days later by partial and two days later again by complete, hemiplegia. In the case reported by myself I have no hesitation in attributing the symptoms to cerebral thrombosis. This diagnosis receives support, not only from the mode of onset, from the absence of cardiac disease, and from the condition of the maternal blood at the time but also from what we may term strong corroborative evidence. I refer to the occurrence of thrombosis in the veins in the lower part of the right leg two days after the onset of the aphasia. Now this thrombosis of the leg took place in the absence of any varicosity of the veins and in spite of the fact that at this time my patient was according to orders, laid up in bed in the recumbent position. The fact that undoubted thrombosis took place in the venous radicles of the lower limb in circumstances most favourable to a perfect circulation is I think, good reason to support the inference that a similar thrombotic accident in the cerebral vessels was the determining cause of the aphasia

[7] Aphasia and Other Speech Defects 1898 pp 118, 119

There is one further argument in favour of cerebral thrombosis as against embolism I refer to the recurrence of the aphasia in a subsequent pregnancy—an event of no uncommon occurrence. Now we know that an embolism is prone to effect the left hemisphere more frequently than the right at the same time it is contrary to all laws of chance that an embolism should be carried to the same spot on the same side of the brain in so many succeeding instances. I think that there is only one inference in regard to the recurrent cases at least—that the first attack of aphasia, whether due to thrombosis or not left histological changes in the vessel wall which formed a seat of election for the development of another thrombus when the vascular conditions were again favourable to such an accident. I trust, therefore, that I have made it quite clear that in a case of puerperal aphasia the occurrence of cerebral thrombosis is no insignificant factor in the production of the affection.

Before dismissing the etiology of puerperal aphasia I would add that the nature of the labour has no necessary relation to the loss of speech. In many of the cases labour is distinctly stated to have been natural and easy It is evident, however that in pyogenic cases and again in cases accompanied by severe hæmorrhage with subsequent anæmia the nature of the labour may contribute indirectly to the occurrence of puerperal aphasia. Sudden emotion seems to be an associated element in several cases This might conceivably be productive of an hysterical loss of speech, or by causing sudden alteration of blood pressure encourage the production of an aphasia from congestive attacks, the detachment of an embolus or the actual deposition of a thrombotic clot. Poupon and Bateman both seem to lay stress on the coincident troubles of lactation present in several of the cases. Such lacteal derangements might be due to vaso motor troubles following the cerebral lesions, but I think hardly concern us in discussing the etiology of the subject.

In considering the *prognosis* of puerperal aphasia one has to bear in mind many facts which apply equally to other forms of speech affection. The nature of the lesion whether functional or organic, nervous or vascular must be taken into consideration. But looking in a general way at the cases which I have summarised in the table one cannot help being struck with the large proportion of recoveries from a primary attack of puerperal aphasia. In some the loss of speech was of a very transitory type, in others complete or partial recovery ensued in the course of a few days weeks or months I have already pointed out that the age of the child bearing woman is an important factor in this group of cases and the vascular conditions are mostly such as to allow of a quick resolution of a thrombus or the rapid opening up of a collateral circulation. A primary attack of puerperal aphasia therefore, will often lend itself to a more or less favourable outlook At the same time the table clearly emphasises the liability to recurrence of the aphasia in the event of a subsequent pregnancy This unfortunate sequence of events took place in both of Finlayson's cases, in Bateman's case and in the cases of Gignoux and Leven reported by Poupon. Moreover the second or recurrent attack in each instance was of a much more serious nature than the attack recovered from in the first instance In both of Finlayson's cases the secondary aphasia remained persistent and in one case was accompanied by permanent rigidity of the paralysed limbs Bateman's case without the development of fresh symptom terminated fatally in six weeks A recurrent attack of puerperal aphasia is therefore a serious matter and the prognosis is grave Indeed it is so bad that we must consider the question whether it ought to be allowed to occur Poupon, in recognising the liability to recurrence of the aphasia in a subsequent pregnancy advises that the woman should be warned to avoid becoming *enceinte* in the future. The cases of Finlayson and Bateman bear further testimony to Poupon's advice. I would go even further and say that in the event of the patient again becoming *enceinte* our only justifiable course according to present knowledge is to terminate the pregnancy at the earliest possible moment Such a procedure was actually carried out in my own case and there has so far been no recurrence of the aphasia

I need not say much regarding the treatment of puerperal aphasia. This will depend to a great extent on the nature of the lesion and the attack must be dealt with on the same lines as guide us in the treatment of any other cerebral affection. It would be superfluous for me to add anything on this score. In addition to special indications for treatment it will in most cases be necessary to pay attention to the general health of the patient, and when signs of improvement manifest themselves to persevere with the re education of the faculty of speech. In regard to the latter point I would only insist that the *séances* should not at first be too frequent and that care be taken not to fatigue the patient. In the event of a subsequent pregnancy I have already expressed the view that for purposes of prophylaxis it is strongly advisable to terminate the pregnancy at the earliest possible moment.

ON THE

ACETONE SERIES OF PRODUCTS IN CONNEXION WITH DIABETIC COMA

By F W PAVY M.D LOND LL.D GLASG F R S

CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

(Continued from p 145)

THE source of the acetone series of products is not as yet definitely determined All are agreed that these products are not derived from carbohydrate. Until lately they have been considered to originate from the nitrogenous grouping of proteid but during the last three or four years opinion has been changing and doubts have been thrown upon the accuracy of this view A point to which considerable importance has been attached is that taking into account the amount of carbon contained in oxybutyric acid in comparison with that contained in proteid more carbon may be found to escape in the oxybutyric acid discharged than can be derived from the proteid metabolised as measured by the nitrogen eliminated. Several observers[1] have recently been looking to fat as the source of oxybutyric acid and there is a decidedly growing disposition to adopt this view The evidence deducible from the research work that has been thus far conducted seemingly points to elimination of the oxybutyric series being influenced by fat ingestion but at the same time it must be said that a want of harmony is traceable in the results that have been recorded and hence that it is not permissible at present to regard the matter as entirely settled.

In the present state of our knowledge our language upon the point under consideration can only be shaped in a conjectural form Assuming the acetone series to be derived from the fatty class of bodies, the question that next presents itself is the mechanism by which the result is reached. If the origin took place in a direct manner from free fat it would be reasonable to expect that a constancy of relation between ingested fat and eliminated oxybutyric acid which is not found to exist, would be met with. If derived from fat existing as an atomic grouping in the protoplasmic molecule analogy may be taken to justify our speaking of its production as a result of faulty metabolism in the following terms

---

[1] Geelmuyden Zeitschrift für physiologische Chemie Band xxiii 1897 Schwarz Archiv für experimentelle Pathologie und Pharmakologie Band xlii., 1899 Waldvogel Zeitschrift für klinische Medicin Band xxxviii., 1899; Hagenberg Centralblatt für Stoffwechsel und Verdauungskrankheiten 1900; Schumann Leclercq Wiener klinische Wochenschrift 1901; and Grube Zeitschrift für diätetische und physikalische Therapie 1902.

Instead of katabolism, or downward metamorphosis, proceeding in an orderly manner to the formation of the normal end products—carbonic acid, water, and ammonia—bodies consisting of final groupings from which no further energy can be extracted, an erroneous shedding from the living proteid molecule of a much higher form of atomic grouping occurs, with the result that latent energy is carried off and wasted through the elimination by the kidney that subsequently ensues. The why and the wherefore of this abnormal cleavage is as yet beyond us to fathom and we can only speak of it as the result of some occult influence brought to bear in connexion with katabolism. It is assumed that there are atomic groupings of different kinds existing in the molecule of living protoplasm and it is conceivable, if fat is regarded as the source of oxybutyric acid, that it is from the fatty grouping that the discharged product is thrown off. When oxybutyric acid is being eliminated another abnormality with regard to it is found to exist. The system loses the power possessed in the normal state of consuming the principle when given by the mouth. It has been found[2] that oxybutyric acid administered even in large quantities becomes lost sight of within the healthy organism. Apparently the system possesses the power of assimilating and thereafter utilising it as it does any other fatty acid. In severe diabetes and in pancreatic diabetes, on the other hand, this power is found to be more or less lost—a circumstance, it may be remarked, which agrees with what is observable in the case of sugar. When sugar is being derived from proteid disintegration the power of assimilating and utilising sugar is contemporaneously lost.

Beyond a little acetone in the urine and a certain amount in the breath the acetone series of products are not met with under normal conditions, but diabetes is not the only abnormal state with which they are associated. Deranged metabolism from faulty nutrient supply seems to be the great general factor concerned in their production. Starvation from whatever cause arising, whether the result of disease or of intentional fasting, is attended with their elimination. They have been recognised in connexion with different diseases of a febrile nature and observation shows that they are more likely to be thus found in children than in adults. Restriction to a proteid and fat diet is also one of the conditions leading to their appearance, and in these circumstances the addition of carbohydrate to the food is immediately followed by their disappearance. Unassociated with diabetes the amount of oxybutyric acid found never runs high. From nine to 10 grammes per diem may be looked upon as constituting an outside quantity and most frequently the amount stands below four or five grammes. In diabetes, as previously stated, the amount may upon occasions reach 150 grammes per diem, or even it may be more than this.

It is mainly as an accompaniment of diabetes that the elimination of the acetone series falls under observation and here it is an event of but too common occurrence. Broadly, it may be said that the disposition in the disease is for the condition to grow into a stage attended with the elimination of the products. In the early stage it is usual for them to be absent. Then as time advances they tend to appear. Progressiveness in this particular is observed to constitute an ordinary feature of the disease. At first the fault is limited to defective assimilative power over the carbohydrates of food. These fail to be put into a fit position for utilisation through, it may be considered, constructive metabolism in connexion with them not being properly carried out. If we are correct, as there is reason to believe we are, in attributing the production of the acetone series of principles to a faulty downward metabolism, the morbid state, when their elimination is taking place, may be looked upon as having extended so as to involve both the upward and downward processes in error, thereby producing the "composite" form of the disorder.

The above may be taken to represent the tendency which inherently exists in connexion with the disease. Much variation, however, with respect to extent of disposition to advance is noticeable in different cases. The progress is observably influenced by intrinsic and extrinsic circumstances. Speaking generally, with reference to the former the younger the patient and the more sensitive the nerve organisation the greater the proneness for the disease to run on speedily into the second or "composite" stage, and when this stage is reached for coma to supervene. Age, as is well known, is a most important item of consideration in connexion with prognosis, and, although exceptional instances from time to time present themselves the appearance of sugar in the urine of young subjects must be regarded as having a very serious meaning. Cases do sometimes occur in which a moderate amount of verifiable sugar is found to be present and in which the usual progressiveness is not observed to follow, but the event is rare. The extrinsic circumstances are resolvable into conditions which exert a disturbing influence upon the general metabolism of the body. They call for attention in detail.

The passage of a large quantity of sugar through the system leads as observation abundantly shows, to general disorder of the operations of life. Sugar is wrongly present in the system and as a result of the toxic effect of this wrongly placed sugar general metabolism is interfered with and transit to the "composite" form of the disease is promoted.

Cases are frequently presenting themselves where evidence can be adduced to show that failure in keeping the elimination of sugar in check by dietetic means is a source of the development of the "composite" condition in diabetes. If the patient has been for some time passing a large amount of sugar—for instance, 50 or 60 or upwards per 1000—the acetone series may be expected to be found and the effect of removing or considerably reducing the sugar may be, within a shorter or longer period, to free the urine from them. In corroboration I will cite the following cases. They are all cases in which at the commencement sugar in large quantity was being passed from want of observance of the proper exclusion of carbohydrate food. The diabetic dietary was in each case ordered to be followed. In some, but not in all, of the cases, as was rendered evident by the analytical reports for sugar, strict attention was at once given to the prescribed dietary. In all, however, the attention given was sufficient materially to reduce the sugar eliminated and greatly to improve the patient's general condition.

CASE 1.—This patient, a man, aged 51 years, was first seen by me on July 11th, 1900. He had been the subject of diabetes for 18 months, and through the disease being allowed to run on uncontrolled he had got into an exceedingly unsatisfactory state of health. The sugar indication by copper reduction was 66 and by the polarimeter 60 per 1000, showing a difference of six due to the neutralising levorotatory effect of the oxybutyric acid present. The ferric chloride reaction for diacetic acid gave a colouration requiring +++ signs for its representation. July 14th: Sugar by copper reduction, 26 per 1000 and by polarimeter, 22 per 1000; and diacetic acid, ++. July 25th: Sugar by copper reduction, 35 per 1000; by polarimeter, 31 per 1000; and diacetic acid, +. August 16th: Sugar by copper reduction, 7.6 per 1000; by polarimeter, 5.9 per 1000; and diacetic acid, 0. Oct. 2nd: Sugar, 0; and diacetic acid, 0.

CASE 2.—The patient, aged 62 years, was first seen on Nov. 16th, 1900. Sugar indication by copper reduction, 76 per 1000; by polarimeter, 72 per 1000; and diacetic acid, ++. Dec. 14th: Sugar, 27 per 1000; and diacetic acid, 0. It will be understood from what has been previously said that absence of diacetic acid implies also absence of oxybutyric acid. Since the last date the sugar has been fairly kept down and when the patient was last seen, June 6th, 1902, the report was sugar, 18 per 1000; and diacetic acid, 0.

CASE 3.—The patient, aged 63 years, was first seen on Oct. 21st, 1899, when the copper reduction indicated 45 per 1000 and the polarimeter 37 per 1000 of sugar, with diacetic acid, +++. On Dec. 14th the copper reduction and polarimeter agreed and indicated 27 per 1000 of sugar; diacetic acid, 0.

CASE 4.—This patient was 57 years of age at the first interview, on March 2nd, 1901, when the amount of sugar found was 91 per 1000 with diacetic acid ++. On March 15th the sugar had become reduced to a trace and the diacetic acid to 0. On April 1st both sugar and diacetic acid were absent.

CASE 5.—The patient, aged 56 years, was first seen on Nov. 9th, 1899. The sugar then was 77 per 1000; oxybutyric acid, 0; and diacetic acid, ++. Nov. 14th: Sugar, 22 per 1000; oxybutyric acid, 0; and diacetic acid, ++. Nov. 22nd: Sugar, 14 per 1000; and diacetic acid, 0. Nov. 30th: Sugar, 0; and diacetic acid, 0.

CASE 6.—The patient, aged 31 years, was first seen on Oct. 31st, 1901, when the amount of sugar found was 83 per

---

1000 with a diacetic acid indication of ++ Nov 2nd Sugar 50 per 1000 and diacetic acid, + On March 11th, 1902, analysis gave sugar 11 per 1000 and diacetic acid 0.

CASE 7 —This patient was 57 years of age when first seen by me on Oct. 19th, 1897 His case then fell in the alimentary type of diabetes. The urine quickly became free from sugar and the patient recovered sufficient assimilative power over carbohydrate to enable him to partake freely of bread and potatoes without passing sugar On Jan 2nd 1901 he came to me with the history that two months previously he had taken cold and had been laid up with bronchitis and influenza. His diet had recently included milk and farinaceous articles somewhat largely and his old symptoms of diabetes had returned. His urine contained 50 per 1000 of sugar with diacetic acid represented by ++ He was placed upon the restricted diet and on Jan. 16th the urine was free from sugar with diacetic acid + On Feb 20th there was neither sugar nor diacetic acid. This state continued and in October it was found that a tolerating capacity had been regained for six ounces of ordinary bread per diem.

It can scarcely be otherwise than that the inference to be drawn from these cases is that the metabolic equilibrium becomes upset by the toxic effect of the abnormal presence of sugar in the system and that by the removal of this influence metabolism may again settle down into an orderly mode of procedure. I think that under the voidance of a large quantity of sugar the development of the double condition may be ordinarily expected to occur as a sequence before any great length of time has passed, but certain cases seem to have more or less of an inherent quality belonging to them which influences the result. I can cite the case of a female patient whom I first saw in 1887 She was then 57 years of age and had already been suffering from diabetes for a year For some time attention was given to treatment and the sugar was kept fairly under At times in 1890 1892, and 1893 exceedingly large quantities of sugar were passed and since this period the quantity has always been more or less large. Extensively diffused neuritis has developed and a certain amount of albumin has appeared in the urine with hyaline and finely granular casts but no diacetic acid has shown itself My last entry is for the early part of last year and then there was an absence of reaction with the ferric chloride test.

(To be concluded.)

THREE CASES OF MOTOR APHASIA FROM INJURY TO THE HEAD, TWO OF WHICH WERE RAPIDLY CURED BY OPERATION

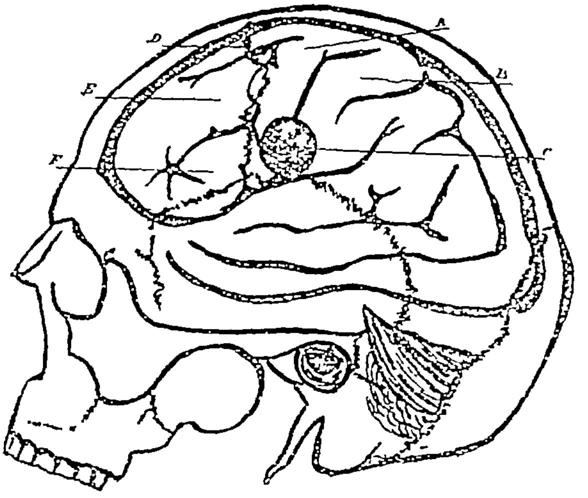
BY DAVID NEWMAN M.D F F P S. GLASG
SURGEON TO THE GLASGOW ROYAL INFIRMARY

IN the first case the injury without producing a fracture of the skull, induced complete unconsciousness followed by epileptiform fits, and while unconsciousness was returning complete paralysis of the right arm and leg appeared. The operation was performed on the tenth day after the accident and the patient was completely recovered from all the symptoms of injury on the twentieth day In the second case the injury had produced a depressed fracture of the skull associated with complete unconsciousness and on the fourth day epileptiform attacks developed involving primarily the right arm and leg On the fifth day the skull was trephined the bone was elevated and blood was removed, and on the twenty-eighth day the patient had completely recovered. In the third case the injury produced aphasia and unconsciousness only there were no fits and no paralysis an operation was not performed and the patient made a slow recovery during four months

CASE 1. *Injury to the head by a fall from a bicycle followed by unconsciousness and incontinence of urine and after three days by epileptiform seizures which at first were few in number but afterwards very frequent consciousness returning showed the presence of motor aphasia; the fits developed in severity and increased in number on the ninth day after the accident partial and on the tenth day complete paralysis of the right arm and leg ensued while the mental condition was improving operation was immediately followed by cessation of epileptiform attacks rapid recovery of movements in the paralysed limbs and complete recovery of speech within a fortnight* —The patient, a man aged 25 years, was cycling on the evening of Feb 5th, 1902, when he was knocked off his bicycle by running into a person on the road. He was picked up unconscious and was sent to the Glasgow Royal Infirmary early on the following morning His condition on admission as recorded by Dr Cuthbert, my house surgeon was as follows He was quite unconscious but when disturbed he resisted in a half voluntary fashion The face was flushed the temperature was 100° F and the pulse 100 rather feeble the pupils were equal and moderately contracted and reacted to light, there was no hæmorrhage under the conjunctiva. From the right ear there was a little oozing of blood but owing to the patient s restlessness on being touched it was impossible to say if the tympanic membrane was injured. There was a little vomiting since admission. On the 9th the patient was still unconscious but very restless the pupils remained quite equal and no bleeding from the ear was observed. In the morning he seemed to understand a little of what was going on but at 11 A M he had a severe epileptiform seizure starting in the right hand and gradually extending over the whole body The twitchings were well marked on the right side of the body and the mouth was drawn to the right side of the face The whole attack lasted only half a minute. He had two similar seizures within two hours. On the 10th the patient had had seven attacks since the previous day but the longest attack only lasted about one minute They all affected the right side first, but in some the twitchings were limited to the face. The patient was still very stupid but seemed to know something of what was going on around him. He opened his mouth when told but could not answer questions although he attempted to do so there was no paralysis and the pupils were equal. On the 11th there was no recurrence of fits and the patient had gained consciousness but could not speak a word. He recognised and shook hands with his mother and seemed annoyed that he could not speak. After this note was made the patient gradually improved in his general condition, he had no more fits until early on the morning of the 13th when he had four slight ones, each lasting about half a minute and only affecting the right side and face The face was much flushed but the temperature was subnormal and the pulse was 56 per minute and of moderate tension There was no paralysis of the muscles of the face or of any part of the body and the pupils were equal and reacted to light He was now quite conscious but still very slow in cerebration He could help himself to milk when it was left at his bedside. When he attempted to reply to a question he made a great effort and got out an inarticulate sound and then shook his head in disgust. He seemed anxious to get a magazine which he held up in front of his face and he was annoyed when it was taken from him His manner and gestures showed that he understood spoken, written, and printed words but he was unable to speak and could not imitate either written or printed words although he made an attempt to do so when asked When his drinking cup was held up and he was asked what it contained he shook his head and pointed to his mouth to indicate that he either could not say the name or that it contained something to drink. When asked if the contents were soup tea, coffee water wine or beer he indicated a negative with a slight shake of the head, but when the word milk" was mentioned he correctly indicated the affirmative and when the word milk was written alongside the others above mentioned he pointed to it correctly On the evening of the 13th at 6 o clock the patient had a severe epileptiform fit and between that time and nine o clock he had 12 attacks these were all similar in character except one in which the convulsive movements were confined to the face. The attacks were characterised not so much by twitching as by rigidity of the muscles of the right arm and leg The patient seemed to know when they were coming on and immediately they were over he was quite conscious When a fit was coming on the face became flushed the pupils dilated and the head turned towards the right side the right hand then became flexed at the wrist and fingers the forearm then became flexed and the whole arm retained a rigid position for about from a minute to a minute and a half this rigidity extended all over the body The patient rolled round on his right side and then almost on to his face with the head much retracted and the left leg was lifted from the bed The attacks commenced again on the afternoon of the 14th at 1 45, 13 fits occurred up to 8 P M On the 15th it was reported that during the previous 24 hours the patient had had 48 attacks, and on that morning it was observed that the right hand was slightly paralysed. During the day the paralysis became more marked, there was no paralysis of the leg or of the muscles of the face From midnight up till 2 P M of the 16th the patient had 18 fits and these were both more severe and more prolonged than formerly The paralysis of the right arm was now complete and the movements of the right leg were greatly impaired, but there was no paralysis of the facial muscles and the pupils were equal

At 2 P M on Feb 16th I trephined the skull a little behind and above the anterior inferior angle of the left parietal bone far enough back to avoid the middle meningeal artery (Fig 1) On exposing the dura mater it was seen to bulge outwards, it was devoid of pulsation and was separated from the brain by a quantity of very dark fluid blood On opening the membrane about an ounce of blood escaped Three tubes were inserted, one passing upwards towards the ascending frontal convolution, one backwards in the direction of the superior temporal, and one forwards as far as the middle frontal, convolution An opening was made in the centre of the skin flap and the tubes were carried through On the evening of the 16th the patient had had no fits since the operation He was now much brighter and considerably improved in general appearance, there was some movement both in the right arm and leg, but the patient remained completely aphasic On the 18th the power had almost completely returned to his right arm and leg, but there was still a little facial paralysis on the right side, there was no recurrence of the fits, and although he was now quite intelligent and conscious he was quite unable to speak. Since the operation a considerable quantity of blood had escaped into the dressings so that they required to be changed twice The cerebral pulsations were now clearly communicated to the drainage tubes, which rested upon the surface of the brain. On the 20th the patient fully understood all that was said to him, but still he was unable to name any objects, figures, or written words which were shown him and could not repeat spoken words or copy writing with the exception of the initial letters of his own name, and even these he did not form correctly When told to do anything, such as to show his tongue, to hold up a certain number of fingers, or to turn to a given page in a book he could do so correctly and he recognised his name when he heard it On the 21st for the first time he was able when asked to repeat his name, but he spoke in a very indistinct way He still continued to improve on the 22nd, although there remained some facial paralysis His speech had improved and he could now use a good many words but not in a correct fashion, although as a rule he succeeded in making his meaning clear On asking him to read printed matter he could make out most of the words, although evidently with some difficulty, and his pronunciation was peculiar, he seemed to stick at small words like *a* and *the* and said that he did not understand them, but he could read written words well. On asking him to write his name he managed successfully to write the initials but generally mis spelt his name In writing a word to dictation he had great difficulty, but when it was spelt for him he started off with a rush while one was still speaking and generally broke down in the middle of the word, and when he got stuck at a word he started off writing his own initials On the 26th the patient continued to improve and he could now make himself clearly understood, although there were a considerable number of words he was still unable to use He read with difficulty, spelling out the words like a child learning to read, some letters he had more difficulty with than others—*y*, *p*, and *w* giving him most difficulty On March 1st he spoke and read fluently, although his speech was perhaps a little clumsy and his reading somewhat syllabic

FIG 1

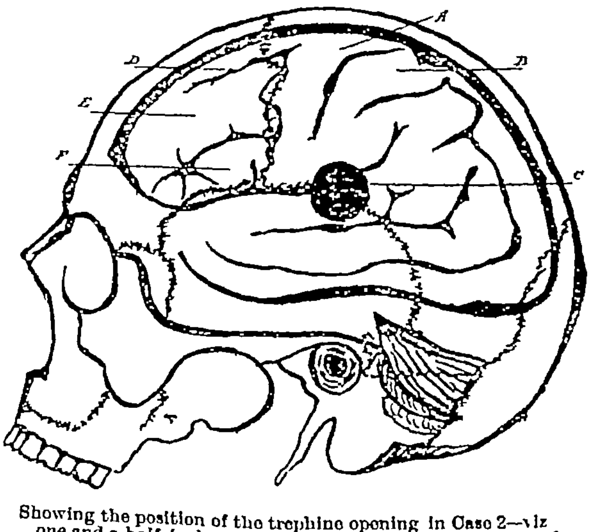


Illustrating the position of the trephine opening in Case 1—viz, at the anterior inferior angle of the left parietal bone A Ascending frontal convolution. B Ascending parietal convolution C Trephine opening D First parietal convolution E, Second parietal convolution F, Third frontal convolution

CASE 2. *Compound fracture of the skull at the anterior inferior angle of the left parietal bone, symptoms of concussion with complete unconsciousness, on the fourth day slight twitchings of the right arm and leg, 10 epileptiform fits in 24 hours, operation followed by return of consciousness and cessation of fits, no paralysis, aphasia remained after consciousness returned, complete recovery on the twenty eighth day after operation.*—A lad, aged 14 years, was admitted into the Glasgow Royal Infirmary on Feb 22nd, 1900 A charge of gelignite was being rammed home in a bore in a coal mine in which he was working The weather at the time was extremely cold and the gelignite was hard and was consequently more explosive than usual While the operator was driving the charge into the bore it suddenly exploded, the operator was killed, two men standing beside him were severely injured and brought into the infirmary, while the patient was struck on the head by a fragment of stone. On admission the patient was found to be suffering from symptoms of concussion Over the anterior inferior angle of the left parietal bone there was a lacerated wound of the scalp At the anterior part and near to the lower border of the parietal bone the aponeurosis was divided and immediately underneath there was a depressed fracture, and from the point indicated a fissured fracture ran forward beyond the reach of the finger From the 22nd to the 26th he remained unconscious, but on the latter date, for the first time, twitchings of the right side of the face were observed, followed by paresis In the evening of the 26th the patient had an epileptiform attack involving the right side of the body with the exception of the leg, there was conjugate deviation of the head and eyes to the right side and both tonic and clonic spasm of the right arm

On Feb 27th I trephined the skull one and a half inches behind the anterior inferior angle of the parietal bone and removed a portion of the parietal and a fragment of the temporal bone (Fig 2.) The patient was so unconscious

FIG 2



Showing the position of the trephine opening in Case 2—viz one and a half inches behind the anterior inferior angle of the left parietal bone and including a portion of the temporal bone Letters as in Fig 1 that the operation could be performed without the aid of an anæsthetic. An hour after being put back to bed the twitchings were observed on the right side of the face, also conjugate deviation of the head and eyes to the right, the right arm also being involved. After 4 30 P M the patient was free from any attacks of epileptiform convulsions until seven o clock on the evening of the 28th when he had a slight attack implicating the face head, and eyes. From the 28th to March 6th the patient had no fits, but when consciousness had completely returned he was found to be aphasic. Showing him familiar objects, such as a cup, a spoon, a knife, or a chair he was unable to name them. He appeared to understand spoken words but was incapable of appreciating anything written or printed he was unable to copy any letters or words he could not write to dictation, nor could he repeat words mentioned to him On March 10th the patient had greatly improved he could now answer questions of a simple character such as his name, his age, and his place of birth but he found difficulty in repeating words read to him. He was unable to read either printed or written words When figures were placed in front of him he could indicate the smaller numbers with his fingers but he was unable to write on paper a corresponding number of strokes to the number shown him. Dr John Love was asked to see the patient the following day and by this time marked improvement had taken place. Dr Love dictated the following note. There is no paralytic symptom of the face, eyes or limbs and no changes of the reflexes superficial or deep. The stereognostic sense cannot be tested on account of the aphasia and slight agraphia. The aphasic condition seems to be purely motor there being neither word nor letter blindness nor is there any blindness for figures Arabic or Roman there is no word-deafness or mind blindness, there is a degree of agraphia. He can write to dictation and also spontaneously he makes some mistakes, such as 'tonnge' for tongue' and 'ding for drink , there is no hemianopsia and the optic disc is normal. As regards the aphasia the patient had greatly improved on the 16th. He was now able to repeat the names of patients who lay near to him in the ward and made a fairly good attempt at the numerals when asked the number of fingers held up or printed figures shown to him. On the 20th the patient was able to repeat the alphabet so as to be understood and to say the numerals correctly, his articulation was not quite perfect but he made rapid improvement in the employment of words although still he had difficulty in writing the letters of the alphabet. In asking him to read, the only letter of the alphabet which seemed to puzzle him was the letter *f* The power of speech had returned on the 27th so that the patient was able to answer any question put to him and he could write an original letter or to dictation as correctly as at any time prior to the accident. He was dismissed on April 25th perfectly well

CASE 3. *Injury to the head by a fall from a bicycle followed by complete unconsciousness and incontinence of urine of one month's duration deglutition difficult no epileptiform attacks and no paralysis of the limbs but evidence of motor aphasia slowly recovering during four months no operation performed slow recovery of speech during four months*—A man, aged 26 years was admitted to my ward in the Glasgow Royal Infirmary on Nov 14th 1899 He was recommended to me by Dr John Mackinnon of Drymen, who supplied me with a very carefully prepared history of the case from which it appears that the patient was riding home from Glasgow to Drymen about 11 P M on Sept 10th, 1899 In going down a hill just past Kilmarnock School he was violently thrown from his bicycle, having run over a man who was lying across the road very much the worse for drink. When seen by Dr Mackinnon at 2 A.M on the following morning he was completely unconscious, but there was no evidence of external injury with the exception of an abrasion on the back of the head, where the scalp was denuded of hair and covered with road dust. This denuded patch was situated about two inches above the external occipital protuberance, one inch to the left of the middle line. There was no indication of the skull being fractured at the point referred to There were no signs of paralysis of the legs the arms or the facial muscles The patient remained completely unconscious until the 25th. During the week from the 18th to the 25th the days and nights were passed in a condition varying from the quietest sleep to extreme restlessness When restless he turned from side to side and generally ended in being completely rolled up in ide his blankets and sheet. He passed urine and fæces involuntarily and while awake he looked a great deal about him but made no sign of recognition On the 25th the patient began to speak, but it was mere gibberish though the sounds had a resemblance to words From this time his general condition began to improve, but during the week from the 26th to Oct. 2nd the evacuations remained involuntary During this week the patient talked a great deal but failed entirely to articulate words. He failed to recognise anyone in particular or to distinguish between different persons. To quote Dr MacKinnon s report, He always called his aunt mother father or sister and also myself Johnnie everybody was Johnnie or Johnnie first or 'Johnnie second. The only other words he used this week were ponens or ponens twice, or twice ponens and sometimes he carried on a long conversation only using the words referred to above and mixing them well he also talked very volubly, using chiefly inarticulate sounds which had not the least resemblance to the English language. During the week ending with Oct. 9th the patient had considerably improved When I (Dr MacKinnon) visited him he would say Good morning Johnnie, thank you very much yes, plea e, thank you He got his photograph taken on the day of the accident in a group along with two fellow workmen who are companions of his. I showed him the photograph and asked him who they were he immediately pointed to himself and said Johnnie first. Who is the next? Johnnie second (real name H—— G——) Who is the third fellow? Johnnie (real name W—— McF——) The photograph also included a bicycle standing in front of the group but he could make nothing out of it. I tried him in reading with the large letters of the alphabet but he did not know a single one This is how he named them A ponens twice, B twice ponens, C Johnnie Pad D Johnnie. He cannot read a single word in the newspapers but simply talks gibberish in the same way as he does with single letters. At this period he was quite unable to recognise relatives. From the 9th to the 16th his general health markedly improved Two companions called to see him during the week he evidently knew them but could not name them and he still failed to recognise any of the letters of the alphabet, although he was able to indicate the use of such common articles as a knife, a fork a spoon a hammer or keys but he was unable to name them or repeat the name when it was mentioned. On the 16th Dr Mackinnon made the following note —

I. *Name and use of familiar objects*—(1) (Showing him a chair), What do you call that?—Johnnie What is it used for? — Nothing that I know very much very much Johnnie to me. Sit down —Does so (2) (Showing him a fork) What is the name of that? — Wee Johnnie before this time What is it for? — Knows quite well. (3) (Showing him bread) What do you call that? Name it. — Johnnie pad to me second this time. What is it for?—Eats it and says Thanks very much (4) (Pointing to his mother) Who is this ?— Johnnie. (He now seems to recognise his mother from a stranger)

II. *The understanding of spoken words* — How are you today?— I am better thank you just now very much than Saturday of course. (I think he has learned this phrase about asking for him because in giving him a sentence that he was unfamiliar with he did not understand it—e g Put on your cap elicited no response What o clock is it ? elicited no response

III. *Does he understand printed or written words?*—I gave him to read in large printed letters Old Gold Cigarett s He read as follows Old Tommy second path second tomas ponen Next tried him with each letter What letter is that, O? — Second pass. What letter is that I ? — What letter is that D? — Johnnie t[illegible] Tommy second.

IV *Voluntary speech*—This is lost as he never asks anything in a coherent manner or gives any information

V *Supposing he does name a printed word correctly does it convey any real meaning to him* —No

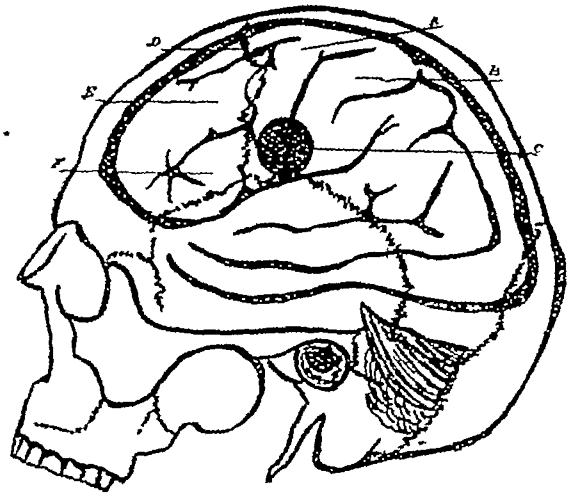
VI *Can he write his name voluntarily?*—I said 'Write your name, he wrote Ddma Hdardrdmas Now I said, read it he read Johnnie Mate second time

VII *Can he copy written or printed matter* —Yes He wrote his name John —— and copied it correctly He can also copy printed words correctly (but of course he does not understand the words he copies)—e g Mixture is what I smoke he wrote MixTure is what I mol e "

VIII *Can he write to dictation?*—Asked to write Is what I smoke he wrote I walt I wake attacks commenced again on the afternoon of the 14th. 1.45, 13 fits occurred up to 8 P.M. On the 15th it reported that during the previous 24 hours the patient had had 48 attacks, and on that morning it was observed that the right hand was slightly paralysed. During the day the paralysis became more marked, there was no paralysis of the leg or of the muscles of the face From midnight up till 2 P.M. of the 16th the patient had 18 fits and these were both more severe and more prolonged than formerly The paralysis of the right arm was now complete and the movements of the right leg were greatly impaired, but there was no paralysis of the facial muscles and the pupils were equal

At 2 P.M on Feb 16th I trephined the skull a little behind and above the anterior inferior angle of the left parietal bone far enough back to avoid the middle meningeal artery (Fig 1) On exposing the dura mater it was seen to bulge outwards, it was devoid of pulsation and was separated from the brain by a quantity of very dark fluid blood. On opening the membrane about an ounce of blood escaped. Three tubes were inserted, one passing upwards towards the ascending frontal convolution, one backwards in the direction of the superior temporal, and one forwards as far as the middle frontal, convolution. An opening was made in the centre of the skin flap and the tubes were carried through On the evening of the 16th the patient had had no fits since the operation. He was now much brighter and considerably improved in general appearance, there was some movement both in the right arm and leg, but the patient remained completely aphasic. On the 18th the power had almost completely returned to his right arm and leg, but there was still a little facial paralysis on the right side, there was no recurrence of the fits, and although he was now quite intelligent and conscious he was quite unable to speak. Since the operation a considerable quantity of blood had escaped into the dressings so that they required to be changed twice. The cerebral pulsations were now clearly communicated to the drainage tubes, which rested upon the surface of the brain. On the 20th the patient fully understood all that was said to him, but still he was unable to name any objects figures, or written words which were shown him and could not repeat spoken words or copy writing with the exception of the initial letters of his own name, and even these he did not form correctly When told to do anything such as to show his tongue, to hold up a certain number of fingers or to turn to a given page in a book, he could do so correctly and he recognised his name when he heard it. On the 21st for the first time he was able when asked to repeat his name, but he spoke in a very indistinct way He still continued to improve on the 22nd, although there remained some facial paralysis His speech had improved and he could now use a good many words but not in a correct fashion, although as a rule he succeeded in making his meaning clear On asking him to read printed matter he could make out most [illegible] difficulty, and [illegible] them, but he c[illegible] *to write his name he manag*[illegible] initials but generally mis-spelt his name. [illegible] word to dictation he had great difficulty, but when it was spelt for him he started off with a rush while one was still speaking and generally broke down in the middle of the word, and when he got stuck at a word he started off writing his own initials On the 26th the patient continued to improve and he could now make himself clearly understood, although there were a considerable number of words he was still unable to use. He read w[illegible] spelling out the words like a child learning to read, [illegible] had more difficulty with than others—*y*, *p*, and *w* giving him most difficulty On March 1st he spoke and read fluently, although his speech was perhaps a little clumsy and his reading somewhat syllabic.

FIG 1.

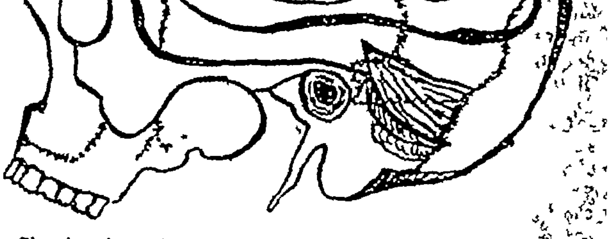


Illustrating the position of the trephine opening in Case 1—viz, at the anterior inferior angle of the left parietal bone A, Ascending frontal convolution B Ascending parietal convolution. C Trephine opening D First parietal convolution E Second parietal convolution F, Third frontal convolution

CASE 2. *Compound fracture of the skull at the anterior inferior angle of the left parietal bone, symptoms of concussion with complete unconsciousness, on the fourth day slight twitchings of the right arm and leg; 10 epileptiform fits in 24 hours, operation followed by return of consciousness and cessation of fits, no paralysis, aphasia remained after consciousness returned, complete recovery on the twenty eighth day after operation.*—A lad, aged 14 years, was admitted into the Glasgow Royal Infirmary on Feb 22nd, 1900 A charge of gelignite was being rammed home in a bore in a coal mine in which he was working The weather at the time was extremely cold and the gelignite was hard and was consequently more explosive than usual While the operator was driving the charge into the bore it suddenly exploded, the operator was killed, two men standing beside him were severely injured and brought into the infirmary, while the patient was struck on the head by a fragment of stone. On admission the patient was found to be suffering from symptoms of concussion Over the anterior inferior angle of the left parietal bone there was a lacerated wound of the scalp At the anterior part and near to the lower border of the parietal bone the aponeurosis was divided and immediately underneath there was a depressed fracture, and from the point indicated a fissured fracture ran forward beyond the reach of the finger From the 22nd to the 26th he remained unconscious, but on the latter date, for the first time, twitchings of the right side of the face were observed, followed by paresis In the evening of the 26th the patient had an epileptiform attack involving the right side of the body with the exception of the leg, there was conjugate deviation of the head and eyes to the right side, and both tonic and clonic spasm of the right arm

On Feb 27th I trephined the skull one and a half inches behind the anterior inferior angle of the parietal bone and removed a portion of the parietal and a fragment of the temporal bone. (Fig 2.) The patient was so unconscious

FIG 2.



Showing the position of the trephine opening in Case 2—viz, one and a half inches behind the anterior inferior angle of the left parietal bone and including a portion of the temporal bone Letters as in Fig 1.

that the operation could be performed without the aid of an anæsthetic. An hour after being put back to bed the twitchings were observed on the right side of the face, also conjugate deviation of the head and eyes to the right, the right arm also being involved. After 4 30 P M the patient was free from any attacks of epileptiform convulsions until seven o clock on the evening of the 28th, when he had a slight attack implicating the face, head and eyes. From the 28th to March 6th the patient had no fits but when consciousness had completely returned he was found to be aphasic. Showing him familiar objects such as a cup, a spoon a knife or a chair he was unable to name them. He appeared to understand spoken words but was incapable of appreciating anything written or printed he was unable to copy any letters or words, he could not write to dictation, nor could he repeat words mentioned to him On March 10th the patient had greatly improved he could now answer questions of a simple character such as his name his age, and his place of birth but he found difficulty in repeating words read to him. He was unable to read either printed or written words When figures were placed in front of him he could indicate the smaller numbers with his fingers but he was unable to write on paper a corresponding number of strokes to the number shown him. Dr John Love was asked to see the patient the following day and by this time marked improvement had taken place. Dr Love dictated the following note. There is no paralytic symptom of the face, eyes or limbs and no changes of the reflexes, superficial or deep. The stereognostic sense cannot be tested on account of the aphasia and slight agraphia. The aphasic condition seems to be purely motor there being neither word nor letter blindness, nor is there any blindness for figures, Arabic or Roman there is no word-deafness or mind blindness there is a degree of agraphia. He can write to dictation and also spontaneously he makes some mistakes such as tonnge for tongue' and ding for drink there is no hemianopsia and the optic disc is normal. As regards the aphasia the patient had greatly improved on the 16th He was now able to repeat the names of patients who lay near to him in the ward and made a fairly good attempt at the numerals when asked the number of fingers held up or printed figures shown to him. On the 20th the patient was able to repeat the alphabet so as to be understood and to say the numerals correctly his articulation was not quite perfect but he made rapid improvement in the employment of words although still he had difficulty in writing the letters of the alphabet. In asking him to read the only letter of the alphabet which seemed to puzzle him was the letter *f* The power of speech had returned on the 27th so that the patient was able to answer any question put to him and he could write an original letter or to dictation as correctly as at any time prior to the accident. He was dismissed on April 25th perfectly well

CASE 3. *Injury to the head by a fall from a bicycle followed by complete unconsciousness and incontinence of urine of one month's duration deglutition difficult no epileptiform attacks and no paralysis of the limbs but evidence of motor aphasia slowly recovering during four months no operation performed slow recovery of speech during four months* —A man, aged 28 years was admitted to my ward in the Glasgow Royal Infirmary on Nov 14th 1899 He was recommended to me by Dr John Mackinnon of Drymen, who supplied me with a very carefully prepared history of the case, from which it appears that the patient was riding home from Glasgow to Drymen about 11 P M on Sept 10th, 1899 In going down a hill just past Kilmarnock School he was violently thrown from his bicycle, having run over a man who was lying across the road very much the worse for drink. When seen by Dr Mackinnon at 2 A.M. on the following morning he was completely unconscious, but there was no evidence of external injury with the exception of an abrasion on the back of the head where the scalp was denuded of hair and covered with road dust. This denuded patch was situated about two inches above the external occipital protuberance, one inch to the left of the middle line There was no indication of the skull being fractured at the point referred to. There were no signs of paralysis of the legs the arms or the facial muscles The patient remained completely unconscious until the 25th. During the week from the 18th to the 25th the days and nights were passed in a condition varying from the quietest sleep to extreme restlessness. When restless he turned from side to side and generally ended in being completely rolled up in side his blankets and sheet. He passed urine and fæces involuntarily and while awake he looked a great deal about him but made no sign of recognition On the 25th the patient began to speak but it was mere gibberish though the sounds had a resemblance to words From this time his general condition began to improve, but during the week from the 26th to Oct. 2nd the evacuations remained involuntary During this week the patient talked a great deal but failed entirely to articulate words. He failed to recognise anyone in particular or to distinguish between different persons. To quote Dr MacKinnon s report, He always called his aunt mother father or sister and also myself Johnnie everybody was Johnnie or Johnnie first or Johnnie second The only other words he used this week were 'ponens or ponens twice, or twice ponens, and sometimes he carried on a long conversation only using the words referred to above and mixing them well he also talked very volubly using chiefly inarticulate sounds which had not the least resemblance to the English language. During the week ending with Oct. 9th the patient had considerably improved When I (Dr MacKinnon) visited him he would say Good morning Johnnie, thank you very much, yes, please, thank you He got his photograph taken on the day of the accident in a group along with two fellow workmen who are companions of his. I showed him the photograph and asked him who they were he immediately pointed to himself and said Johnnie first. Who is the next? Johnnie second (real name H—— G——) Who is the third fellow? Johnnie (real name W—— McF——) The photograph also included a bicycle standing in front of the group but he could make nothing out of it. I tried him in reading with the large letters of the alphabet but he did not know a single one. This is how he named them A, 'ponens twice, B twice ponens C Johnnie Pad D Johnnie. He cannot read a single word in the newspapers but simply talks gibberish in the same way as he does with single letters" At this period he was quite unable to recognise relatives. From the 9th to the 16th his general health markedly improved Two companions called to see him during the week he evidently knew them but could not name them and he still failed to recognise any of the letters of the alphabet, although he was able to indicate the use of such common articles as a knife, a fork a spoon a hammer or keys but he was unable to name them or repeat the name when it was mentioned. On the 16th Dr Mackinnon made the following note —

I *Name and use of familiar objects* —(1) (Showing him a chair) What do you call that?'— Johnnie What is it used for? — Nothing that I know very much very much Johnnie to me. Sit down —Does so (2) (Showing him a fork) What is the name of that? -- Wee Johnnie before this time What is it for? — Knows quite well. (3) (Showing him bread) What do you call that? Name it — Johnnie pad to me second this time What is it for? —Eats it and says, Thanks very much. (4) (*Pointing* to his mother) Who is this ?— Johnnie (He now seems to recognise his mother from a stranger)

II *The understanding of spoken words* — How are you today?— I am better thank you just now very much than Saturday of course. (I think he has learned this phrase about asking for him because in giving him a sentence that he was unfamiliar with he did not understand it— e g Put on your cap elicited no response What o clock is it? elicited no response.

III. *Does he understand printed or written words*'—I gave him to read in large printed letters Old Gold Cigarettes He read as follows Old Tommy second path second tomas ponen Next tried him with each letter What letter is that, O? — Second pa s. What letter is that I ? — Tommy second. What letter is that D? — Johnnie t p'

IV *Voluntary speech* —This is lost, as he never asks anything in a coherent manner or gives any information

V *Supposing he does name a printed word correctly does it convey any real meaning to him* —No

VI *Can he write his name voluntarily*'—I said Write your name, he wrote Ddma Hdardrdmas. Now I said read it he read Johnnie Mate second time

VII *Can he copy written or printed matter*'—Yes. He wrote his name John —— and copied it correctly He can also copy printed words correctly (but of course he does not understand the words he copies)—e g, Mixture is what I smoke he wrote MixTure is what I smoke

VIII *Can he write to dictation*'—Asked to write, Is what I smoke he wrote I waht I wake

IX. *Can he repeat words?*—No, I said, 'Say mother,' but he could not do it and made an attempt by saying, 'on a top i.'

Nov 7th, 1899—Patient's general health has improved very much within the last three weeks He sleeps well and eats well and is fond of work He has been doing little jobs in connexion with his trade as a joiner and knows quite well what he means to do, and also the use of his tools He sleeps well, is quite cheery and happy, and whistles lots of familiar tunes, but never tries a song I have often tried him to sing a verse of a song, but he never would attempt it He knows his people better now, but still calls them 'Johnnie' or 'the old ane' I again tested his condition to night, pretty much in the same lines as before (*vide* Oct. 16th) Knee-jerks are good.

I *Name and use of familiar objects*—(Showing him a pen), 'What is that?' Reply, 'The red one' (Showing a pocket knife), 'What is that?'—The top or red one' (Showing a bunch of keys), 'The top' (Showing a watch), 'The top part' (Showing a plant), 'The red one'

II. *Ability to read*—(1) Printed matter and asked to read the following 'All fat people,' he read, 'All at person.' Asked to name each letter, he knew them all with one exception Asked to read, 'A soldier in camp,' he read, 'A person in at' (2) Written matter—I wrote the following letter to him and asked him to read it, what he read being in parentheses 'Drymen, 7 November, 1891 (Johnnie, 11 Up, 1891)—Dear John (That on), Was it raining to day? (Was it again to day?), Did the river overflow its banks? (Did the person up at things?), Would you like to go to London? (Would you like to go to things?), or Africa at present? (or top at things?)' Asked to read his name he knew it at once. (3) Figures He can name most of the figures correctly, can do a little addition, but cannot manage subtraction Asked to add 32,453 to 24,621 he gave the answer correctly, 57,074 Asked to subtract 214,346 from 437,896 he gave the answer wrong, 650,122.

III. *Can he write volitionally?*—No, this is absolutely lost.

IV *Can he write to dictation?*—No, this is absolutely lost

V *Can he write figures when dictated?*—Yes, partially, he wrote straight on to 28, but could not write them correctly if not given seriatim.

VI *Does he understand spoken speech?*—Yes, partially, if asked to put out his tongue he does so, and when asked to sit down on a chair he did so If assisted by gesture he knows at once what is meant

VII *Does he understand written matter?*—No, but he can copy it correctly I wrote on a piece of paper, 'This was a very wet day,' and he copied it correctly

VIII *Can he copy printed matter?*—Yes The following observations were made as to interruptions in sensory centre

I *Understanding of speech*—When spoken to no doubt he understands many words, but still there is marked impairment

II. *Understanding of writing*—This is absolutely lost

III *Understanding of printed matter*—He can *name* some of the smaller words correctly, but they convey no intelligent meaning to him

IV *Can he repeat a word spoken to him?*—No, occasionally after many attempts he may hit on it, but he would much rather prefer that you would accept a substitute. I asked him to say 'lamp' and after a few attempts he said 'lama.' This is a proof that he has no intelligent conception of written words word blindness I wrote on a slip of paper the following request in large plain letters, 'Please give me a small' (his reading was, 'Things again me a person') 'bit of tobacco ('vet of things')? He had no idea that tobacco was wanted Then I wrote, 'Will you be kind enough' (he read, 'Will you be again things') 'to give me the loan of' ('to things me to things of') 'your pocket-knife' ('our tops things')? This conveyed no idea to him that I wanted his pocket knife. 'What time is it on' ('That time is it on) 'your watch ('our things')? Even when shown a watch he does not know the time on it. *Note*—It will be seen from this examination that he has improved a good deal from the time he began to go about."

When admitted to the Glasgow Royal Infirmary he was still very aphasic and had but a limited and very incorrect vocabulary He was, however, quite cognisant of his inability to speak and after he came out with false words evidently appreciated their inapplicability He could pronounce his own name, but when asked where he came from he spelt the name of the town and failed to pronounce it He could tell the days of the week and count the numerals and his figuring was perfect, and he could add correctly but he used his fingers to count He knew the comparative value of coins but could not correctly state their worth. He could read only short words and when asked what caused his accident he was unable to say, but when pressed for an answer he drew the picture of a bicycle During his residence in the infirmary he made rapid improvement and the case not being one demanding surgical interference the patient was transferred to Dr Middleton's ward. When he was dismissed therefrom on Dec 29th he could speak fairly well and could remember the nature of the accident which led to his injury The patient was seen by me several times since he was dismissed and in May, 1900, he was perfectly well

Glasgow

A REPORT ON 43 CONSECUTIVE CASES OF DIPHTHERIA

By S GURNEY CHAMPION, M.B, C M EDIN,
HOUSE PHYSICIAN, NORFOLK AND NORWICH HOSPITAL

AND

A. LL. VAUGHAN, M R C S ENG, L R C P LOND,
LATE HOUSE SURGEON, NORFOLK AND NORWICH HOSPITAL

IN publishing the statistics of 43 consecutive cases of diphtheria admitted to the Norfolk and Norwich Hospital during the past two years, it is our intention to show the value of tracheotomy and free administration of antitoxin in the treatment of this disease The cases admitted to this hospital were those suffering from laryngeal obstruction and many of these were brought here *in extremis* In these circumstances it will readily be understood that 39 out of the 43 cases required operation The total number of deaths will be seen to be 10 out of which five cases—i.e., one half—were aged between one and two years, two between three and four years, while the total number of patients admitted at these ages was 12 and 14 respectively, thus showing a mortality of 41⅔ per cent. at the former age and only 14 per cent. at the latter age But of these 43 cases it will be seen that 24, or rather more than one half, had a laryngeal and pharyngeal infection, while 14 had laryngeal infection alone, with a mortality in the former case of 16 per cent and in the latter of nearly 50 per cent., it is, however, only fair to state that out of the six deaths occurring in the latter (laryngeal alone) variety—one was due to suppression of urine, two were due to broncho-pneumonia, while of the other three two patients died from asphyxia and one from hæmorrhage into the trachea which was started during a fit of coughing within a few hours of the operation Three cases which recovered had a laryngeal, pharyngeal, and nasal infection All the patients who recovered were examined as late as three weeks after discharge from the hospital for signs of paralysis, and in three only was any present.

STATISTICS

The total number of cases was 43 Tracheotomy was performed in 39 cases, the result being that 29 of the patients recovered and 10 died (one child had ceased breathing before the operation had begun) Paralysis occurred in three cases, all recovered completely One patient had a pharyngeal infection alone, no antitoxin was administered and the paralysis occurred 25 days after the onset of the disease One patient had a pharyngeal, laryngeal and nasal infection, 17,000 units of antitoxin were injected and paralysis occurred on the fifty fourth day of the disease In a third case the patient had pharyngeal and laryngeal infection, 6000 units of antitoxin were administered and paralysis occurred on the fifty seventh day of disease. Cultures were taken in 18 cases showed the following result in five cases there was a pure culture of diphtheria, in six a mixed culture of diphtheria and staphylococci, and in seven pure cultures of staphylococci or mixed staphylococci and streptococci.

TABLE I.—*Age and Incubation Period*

Age in years	Number of cases.	Days ill before admission.	Number of cases.
Under 1	1	1	6
2	12	2	7
3	4	3	6
4	14	4	5
5	7	5	4
6	3	6	1
Over 10	2	7	6
		8	5
		11	1

TABLE II.—*Seat of Infection and Day of Removal of Tracheotomy Tube*

Varieties of infection	Number of cases.	Day on which the tube was left out	Number of cases
Pharyngeal	2	Second	6
Laryngeal	14	Third	12
Pharyngeal and laryngeal	24	Fourth	6
		Fifth	2
Pharyngeal laryngeal and nasal	3	Sixth	1
		Tenth	1
		Fourteenth	1
		Twenty third	1

TABLE III.—*Date of Appearance of Rash and Amount of Antitoxin Injected.*

Number of days after injection of serum before the appearance of rash	Number of cases	Number of 1000 units of antitoxin injected
3	1	6
6	1	15½
7	1	32
8	3	27 9 9
10	2	7 12
11	1	13
12	1	8
13	1	17
16	1	10
17	1	6
31	1	3

Rash occurred in 14 cases In 11 of these cases the rash was an irritable urticaria with some erythema surrounding the wheals varying in distribution and extent from a few patches on the knees or abdomen to a profuse rash affecting the face, the limbs, and the trunk. In only one case was there constitutional disturbance—namely rise of temperature and malaise. In three other cases an irritable small papular eruption was noticed over the limbs and in one of these the rash was accompanied by pyrexia and vomiting Albuminuria was found in 30 cases of the remaining 13 cases six definitely had none while in the other seven cases no urine could be collected The amount of albumin varied from one-half in one case to a mere trace, the average being a definite deposit after boiling and allowing the coagulum to settle.

Complications—In seven of the fatal cases the complications were as follows pharyngeal infection after laryngeal arising on the fifth day after admission and an injection of 6000 units of antitoxin in one case hæmorrhage following tracheotomy in one case broncho-pneumonia in two cases suppression of urine in one case asphyxia in one case (prior to tracheotomy) and cardiac failure in one case. In the non fatal cases the complications were broncho-pneumonia in four cases, otorrhœa in one case subcutaneous emphysema in one case paralysis in three cases, and diphtheritic infection of the nose and of the wound in one case (this case is mentioned in detail later) Accidental complications present were congenital syphilis, measles, and old pleurisy with a contracted chest.

Length of stay in hospital—The length of stay in hospital in the fatal cases was less than 24 hours in six cases two days in one case three days in one case five days in one case and six days in one case. As regards the recoveries the average number of days the patients remained in hospital was 33, the longest period being 47 days and the shortest 12 days

TREATMENT

Tracheotomy—In no case was an anæsthetic employed the patient's head being fixed in Caiger's head rest and the limbs being bound to the table by bandages Special attention was paid to dividing all the layers in the middle line to avoid closure of the tracheal wound by overlapping tissues and thus facilitating the earlier removal of the tube as the wound then remained patent for breathing purposes for several days.

Tube.—Parker's silver tube was employed in all cases, it being removed for cleansing at the end of from 24 to 48 hours and then either replaced or substituted by a rubber one if any tube was found necessary At the end of 48 hours an attempt was always made to leave out the tube entirely In six cases the attempt was successful and in 24 out of the remaining 30 which survived permanent removal was effected on the fourth day In one case in which the tube could not be removed till the tenth day there was still abundance of membrane being coughed up causing much dyspnœa during expectoration In two other cases the dyspnœa and recession during sleep were such as continually to awaken the child on which account it became necessary to replace the tube, though during the waking hours the breathing was absolutely unembarrassed. One of these cases was treated with a mixture of tincture of belladonna bromide of ammonium, and compound tincture of camphor with marked success, the child sleeping easily without the tube on the following night The other case where the tube could not be removed until the twenty third day was much benefited by attempted intubation which, though not complete apparently removed some obstruction existing in the larynx

Antitoxin.—An initial dose of 6000 or 8000 units—i.e. from 20 to 30 cubic centimetres of Parke Davis's preparation—was employed and in few cases it needed repetition The indications relied on for pushing the antitoxin were (1) persistent rise of temperature with other signs of toxæmia (2) abundance of membrane and dry inspissated mucus (3) broncho-pneumonia and (4) spread of disease and re infection. The temperature usually responded to the initial dose and reached the normal by the third or fourth day after a gradual decline. In several cases dry inspissated lumps of mucus gave rise to as much trouble as pieces of membrane and required the use of mechanical means for their removal from the trachea. In these cases also pushing the antitoxin was followed by marked success In all cases of broncho-pneumonia small doses—i.e 2000 units—were given once or twice daily until the temperature began to fall. One child had altogether 18,000 units of antitoxin during the first five days of treatment with a resulting cure the temperature which had been previously sustained gradually falling to normal after this date. (The chart of this case is published with this article.) The average dose given was 9400 units with a maximum of 33 000 and a minimum of 2000 units Two cases in which 6000 and 21 000 units were given respectively developed further disease the former a pharyngeal after a laryngeal infection with a fatal result and the latter a nasal and wound infection following primary disease in the pharynx and larynx The patient in the latter case was discharged cured but has since been re admitted owing to the breaking down of the tracheotomy wound which however slowly healed under treatment. Short notes of this case are published

Stimulants—These were freely administered brandy strychnine given hypodermically and carbonate of ammonia being those relied on.

Expectorants were given in every case squills ipecacuanha, tolu, &c. being those chosen Under this heading may be included a steam spray of solution of sodium bicarbonate, which was administered as a routine every half hour for the first 24 to 48 hours or longer if the indications persisted. The atmosphere of the tent in which the child was nursed was further moistened by the steam from a bronchitis kettle

Local treatment —The pharynx or the nose was swabbed or syringed with antiseptic lotions of carbolic acid (1 per cent.) or boro glyceride where there was persistence of membrane after 48 hours of treatment.

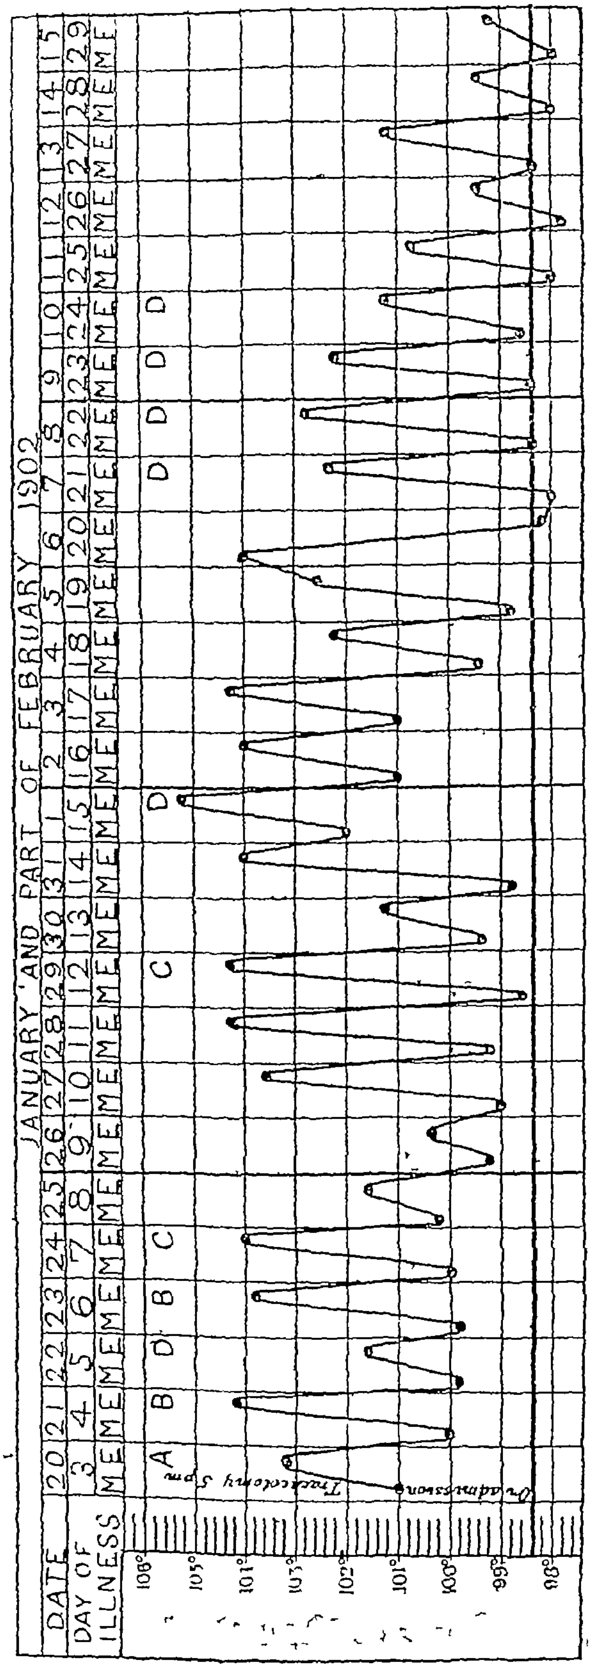
Indications for tracheotomy —(1) Recession of the intercostal spaces, the lower ribs, and the clavicular fossæ was considered to indicate the necessity for tracheotomy, and (2) restlessness with dyspnœa were always regarded as most urgent symptoms and when present it was our rule to operate without delay In no case was cyanosis waited for

The following case appears to us to be of sufficient interest to warrant the publication of short notes of it

The patient was a female, aged one and a half years, and was admitted on the third day of her illness with a history of stridor and dyspnœa for two days On admission there were diphtheritic membrane on the right tonsil and evidence of advanced laryngeal obstruction Tracheotomy was performed within an hour of admission—a No 2 silver tube being inserted—and several pieces of membrane were coughed up at the time A culture taken from the trachea showed mixed diphtheria bacilli and staphylococci No anæsthetic was used The temperature had then risen from 100° to 103° F, while the pulse rate was 160 and the respiration rate was 40 per minute. An initial dose of 5000 units of antitoxin was given and for the next four days the antitoxin was repeated, 18,000 units being administered during this period On the fifth day the temperature had fallen to 101°, the pulse rate to from 130 to 140, and the respiration remained about the same There was at this time evidence of broncho pneumonia which was limited to the right lung and the child was passing a very small amount of urine. On the next day the temperature was still lower The antitoxin was discontinued and the tracheotomy tube was removed The child breathed easily through the wound and was much improved in her general condition On the following day a transient urticarial rash appeared over the limbs and the trunk, and the temperature rose to 103 6°, but there was no increase of the symptoms of the disease until the next day when the child developed a nasal discharge from which a mixed growth of diphtheria bacilli and staphylococci was obtained and at the same time the left lung became affected with pneumonia On this evening and also the following one the temperature reached 104° and the rash persisted. A further dose of 3000 units of antitoxin was given and the temperature remained at 101·2° instead of rising as it had done previously to 104°, while the rash had much increased On the eleventh day the temperature again rose and for the succeeding three days it oscillated between 101° and 105° The child was now continuously ice-cradled and frequently sponged with tepid water and a further dose of 2000 units of antitoxin was administered on the twelfth day In spite of the high temperature the child's general condition remained good, she took nourishment well but occasionally vomited. On the fifteenth day a second eruption appeared This was a hæmorrhagic rash situated over the dorsum of the hands and feet and the extensor surfaces of the lower half of both legs The patches were bright red and varied in size from that of a pin's head to that of a shilling and spread rapidly at the margins This was thought to be an antitoxin rash, so no more of this remedy was given, and the rash faded in two days, the patches changing colour like a bruise. On the eighteenth day the tracheotomy wound, which had shown no sign of healing, was covered by a definite diphtheritic membrane, from which a mixed growth similar to the previous ones was obtained. As the temperature remained high and the pulse rapid antitoxin was again administered, 2000 units being given daily for four days, with the result that the temperature gradually fell. After the second injection the ice-cradle could be dispensed with and after the fourth all membrane had disappeared from the wound which then rapidly healed On the twenty sixth day the child was first noticed to have an intermittent internal squint with the left eye, the knee-jerks, however, were brisk and there was no sign of paralysis of the soft palate From this time onwards the temperature remained normal except for an occasional slight rise and the child appeared to be quite well At the end of five weeks she was discharged. The wound was then healed but on coughing there was bulging of the scar A fortnight later she was brought back. The wound had reopened sufficiently to admit a probe easily and mucus was being coughed through it Her general condition was unsatisfactory. The knee jerks were absent but there was no further evidence of post-diphtheritic paralysis The child is still under treatment as the wound is not yet sufficiently healed

The temperature chart of this case is appended

We are indebted to the courtesy of Dr Barton, Dr F W Burton Fanning, and Dr Long for permission to publish the notes of these cases



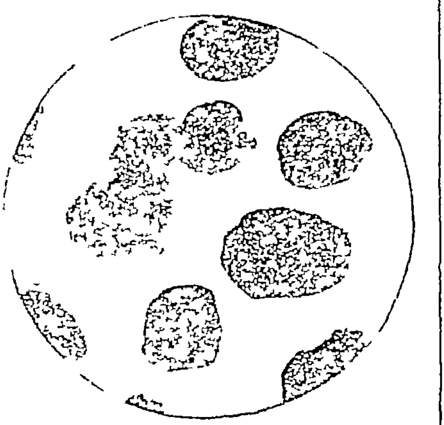
A, 5000 units of antitoxin administered B, 4000 units of antitoxin administered C, 3000 units of antitoxin administered D 2000 units of antitoxin administered

NOTE ON A CASE OF "TRUE" INTESTINAL SAND

BY CHARLES H. BEDFORD, D.Sc., M.D. EDIN.,
PROFESSOR OF CHEMISTRY, MEDICAL COLLEGE, CALCUTTA; CHEMICAL EXAMINER TO GOVERNMENT, BENGAL; MAJOR, INDIAN MEDICAL SERVICE.

So little is known of this condition, if we may judge from the paucity of references to the subject in contemporary medical literature, that it becomes of interest as well as of importance to record any case of the kind, more especially when the report is supplemented by a chemical analysis. Through the kindness of Lieutenant-Colonel F. S. Peck, I.M.S., of Calcutta, I lately have had the opportunity of analysing a specimen of "true" intestinal sand which was passed by a patient seen several times by him in consultation, and I am further indebted to him for furnishing me with the clinical facts of the case.

The patient was a European woman, aged about 44 years, with a very marked history of gout. She had had a large number of "gouty deposits" in the smaller joints, with nodules in the ears, but the larger joints did not appear to have been affected. Several tendons had also been disabled from the same cause. Constipation was present, requiring treatment with saline purgatives. The motions were ordinarily normal in appearance except for the presence of mucus. There was apparently no diarrhoea alternating with constipation, as was sometimes the case in such patients. There was, however, a distinct, though not severe, attack of muco-colitis coincident with the passage of the sand. There was no history of colicky pains, vomiting, or distension. There was never any intestinal pain to speak of. "The tongue was always particularly clean." She had not reached the menopause, was sterile, and had all her life suffered from ovarian pain. A sample of her urine was analysed by me in March last and had a brown, somewhat smoky appearance, with much suspended matter; the specific gravity was 1020, acid reaction, much albumin was present with a few fibrinous casts and uric acid crystals. Lieutenant-Colonel Peck mentions the fact that the albuminuria entirely disappeared some months later. At the time the sand was passed she had for months been on milk and farinaceous diet. The treatment was by preparations of lithium, occasional saline purgatives, and colchicum and iodide of potassium in mixture. The amount passed at any one time seems to have been not more than half a teaspoonful (usual size).



Showing shape of sand granules when viewed under the microscope.

On examination the deposit was found to be very finely granular and yellowish brown, and very like fine sand. Under the microscope the particles were of very various shapes and sizes—oblong, irregularly oval, and of the other shapes shown in the diagram. The colour varied from black through reddish brown to a light yellow. Many of the particles were only translucent at the edges. There was no appearance of vegetable or crystalline structure. The organic portion, washed and stained with methylene blue, showed a quantity of cocci and bacilli. The result of analysis is as follows: moisture, 5·20 per cent.; calcium phosphates, 28·63 per cent.; calcium carbonate, 5·20 per cent.; magnesium phosphate, 0·49 per cent.; and organic matter, 60·43 per cent. No traces of urates or uric acid were detected. The amount of sand remaining over was too small to allow of a sufficiently accurate examination to be made as to the nature of the pigment present. True intestinal sand appears to yield a vastly higher percentage (from 28 to 70) of inorganic constituents than does the false variety, which gives only about from 2 to 3 per cent. generally.[1]

The above analysis, then, clearly shows that we are dealing in this case with an example of "true" intestinal sand as distinguished from the "false" sand which owes its origin to undigested vegetable particles (generally sclerenchymatous) occasionally coated with earthy salts. Pears, figs, and bananas are apparently specially liable to produce this "false" variety, which was, I believe, first described in England by Professor S. Delépine at a meeting of the Pathological Society of London in 1900. One of the most recent as well as one of the best papers on the subject is by Sir Dyce Duckworth and Dr. A. E. Garrod, published in the Transactions of the Royal Medical and Chirurgical Society, 1901, to which is appended a bibliography.

The case now recorded agrees with M. Dieulafoy's series in having occurred in a gouty middle-aged woman (about two-thirds of his cases are women about 35 years of age) and as regards the history of concurrent muco-colitis. The absence of painful paroxysms, vomiting, and flatulence is interesting, as in most recorded cases these symptoms have been marked. The albuminuria (with granular casts and uric acid) was also apparently a gouty manifestation in this case.

In the discussion which followed Duckworth's and Garrod's paper[2] Dr. A. Crombie, late of Calcutta, expressed the opinion that the affection must be commoner in India than in England and he mentioned the fact that in 10 years' experience at the Presidency General Hospital, Calcutta, he had met with three cases, all accompanied by severe colic which varied directly with the quantity of sand passed. It is to be regretted that there is nothing to show that these cases were examples of "true" intestinal sand or "enteric lithiasis" as the condition has been termed, for in the "false" cases colicky pain varying directly with the amount of sand passed is also a prominent feature and there is no mention of any other circumstance which would guide us to a knowledge of the true nature of Dr. Crombie's cases, as apparently there was no chemico-microscopical examination made in any of them.

The cause of true intestinal sand.—The relatively large proportion of lime salts is noteworthy. Bunge has pointed out that the proportion of lime present in milk exceeds that to be found in an equal bulk of lime-water. Hence in cases which have been for long on an almost exclusively milk diet the source of the large proportion of lime salts present in true intestinal sand is to some extent explained. The intestine is moreover now known to be one of the main channels for the excretion of calcium salts from the system. And the "chalk stone" deposits present in gout contain in addition to their principal constituent (sodium urate) varying proportions of the phosphates and urate of calcium. As true intestinal sand appears to be closely associated with gout and apparently has not been observed in non-gouty patients who for long periods have been placed on an almost exclusively milk diet, one is inclined to regard the condition as allied in some respects to the tophaceous deposits in other parts. But how are we to explain the absence from the sand of uric acid and its compounds which so characterise the gouty deposits in other parts of the body? It is easy to conjecture that the inorganic constituents of the sand are derivable from the milk diet and by excretion into the bowel from the system, and that, on the other hand, uric acid and its compounds are excreted by the kidneys, and to a small extent by the skin, and separate out in those tissues in which the blood supply would appear to have a greater opportunity of depositing them than would be the case in the intestine. Sluggish action of the bowels is alleged as a cause of intestinal concretions, but this can only be a predisposing circumstance, for the milk diet and the sluggish state of the bowel do not alone appear to be able to bring about the condition of true intestinal sand All, then, that we can say at present is that the condition would appear to be very closely related to gout and to be favoured by a milk diet

---

[1] An exception to this occurs in the case of the [illegible] found in the intestines of people fed on bread made from oat bran. These concretions yield often some 15 to 0 per cent. of oat-bran [illegible] 60 to 0 per cent. of phosphates of calcium and magnesium and a small percentage of fats and soaps.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

NOTE ON A CASE OF SPRUE

By R. MUZIO WILLIAMS, M D LOND,

AND

M H SPENCER, M D CANTAB

WE thought that the following short account of this case might be of interest, more especially as the diagnosis of sprue appears still to be frequently missed, for though the patient had evidently had the disease for some time and had seen at least eight or nine medical men it had never been even suggested as being sprue

The patient, a woman, aged 42 years, came into a home on May 4th last, having landed from India on the same morning The only serious illness she had had previously to the present one was an attack of severe diarrhœa 10 years ago which lasted for some months and necessitated her return home from India where she was then residing During the last four years she had suffered from intermittent diarrhœa, with increasing weakness and emaciation, at times, however, partially recovering for a period and regaining some of the weight which she had lost. The stools were not very frequent—generally only four or five daily—semi solid, fermenting in character, and of a light yellowish grey colour She had complained of a sore condition of the mouth and tongue for some time In spite of periods of intermission the disease progressed insidiously, and at the time of her return to England she was exceedingly emaciated and in a very feeble condition During the last month, whilst on her voyage home, the bowels were somewhat constipated and enemata were generally necessary to secure an action

On admission she was extremely emaciated and profoundly anæmic The skin was drawn tightly over the face and bony points of the body and was pigmented of a dirty brown colour, the pigmentation being specially marked on the neck and face The pulse was feeble, 92, and the temperature was subnormal only on one occasion reaching 96 4° F The slightest movement caused syncopic attacks The heart was not enlarged. There were loud blowing murmurs with systole and diastole over the apical region not conducted into the axilla. The spleen was not felt. The liver was felt for two fingerbreadths below the costal margin and the upper margin of dulness commenced at the sixth interspace The urine contained a trace of albumin Dr Patrick Manson kindly examined the blood and reported as follows "The blood is that of simple anæmia, a few poikilocytes present but nothing like pernicious anæmia." The tongue was white and glazed and completely denuded of epithelium, the buccal mucous membrane was in a similar condition, and there were two small ulcers near the anterior pillars of the fauces The conjunctivæ were pearly white. She took nourishment fairly well. The following day, after consultation with Dr Manson, as her pulse was rapidly becoming worse she was infused by Mr Abbott with two pints of normal saline solution containing one tenth of a grain of strychnine sulphate and three drachms of brandy After this her pulse improved a good deal and she expressed herself as feeling much better Two hours later, however, she had another syncopic attack and died

A post-mortem examination was made by us 20 hours after death The body was extremely emaciated, there being hardly a trace of fat left in the tissues. The lungs were entirely free from adhesions, crepitant throughout, but markedly bloodless, there was no trace of tuberculous deposit present in them There was a small quantity of clear fluid in the left pleural cavity The heart was somewhat atrophied but, contrary to expectation, the ventricular walls did not show any marked attenuation There was no naked eye appearance of degenerative change in the muscle or endocardium, the valves were competent and healthy The liver, unlike what is generally found in these cases, was somewhat enlarged, greasy and fatty, easily breaking down on pressure with the thumb The pancreas was firm and rather tough on section, suggesting some fibrotic change. This has been noted in other cases reported. The spleen was small, firm, and pale The kidneys were firm and markedly anæmic, the capsule peeled readily, and the surface was not granular The whole intestinal tract from the duodenum to the rectum was extraordinarily thinned The bowel contained a quantity of slimy mucus On washing this away the mucous membrane was found to be practically absent. In the small intestine and cæcum the bowel wall was so thinned as to be transparent when held up to the light and so friable as to tear very readily on handling This diaphanous condition of the bowel was marked through its whole extent but most noticeable in the small intestine and cæcum In places there were small diverticula formed owing to the extreme attenuation of the walls. They were of about the size of a walnut and could hardly be touched without tearing The omentum contained scarcely any fat. There was no enlargement of the mesenteric glands The stomach was dilated and full of undigested fluid, it was thin walled and perfectly white. There was no ulceration present in any part of the alimentary tract. The pelvic organs were normal with the exception of two small parovarian cysts and there was no sign of previous peritonitis

A CASE OF DERMATITIS CAUSED BY HUMEA ELEGANS

BY WALTER CARRINGTON HEARNDEN, M R C S ENG

THE following case may be of interest to some of the readers of THE LANCET as it illustrates the difficulty of fixing the cause of certain skin eruptions

A female patient of mine who has a particularly delicate complexion, has during the last few months been frequently suffering from vesicular eruptions on the nose and cheeks looking like impetigo They quickly subsided under treatment but as there was an almost immediate relapse she consulted a specialist who diagnosed eczema and naturally ordered a course of arsenic On June 7th I found her with a red, swollen face, the left eye closed, large vesicles containing clear serum on the cheeks, and a patch of eczema on the left side of the chin. She was greatly alarmed as she supposed that she had erysipelas Her temperature, however, was normal. She was unable to account for the attack, but first noticed it after playing ping pong She had not been handling *Primula obconica* as she was aware of its dangers, but she volunteered the statements that she had been feeding chickens with crushed bones and that she had noticed some irritation about the nose The attack subsided in the course of a few days under lotio plumbi subacetatis The first time she went out, at the end of the week when her face was well, she complained of itching of her right eyelid and in the course of a few hours her face was as bad as ever She then said that she had picked a leaf of *Humea elegans*, and had smelt it and that she had been in the habit during the last few months of picking a leaf and rubbing it on her veil as she liked the perfume The position of the rash was just where a veil would touch the face and the patch on the chin corresponded to the place where the veil is screwed up and tucked in No doubt this had been the cause of all the trouble

Humea elegans, a native of New South Wales, is frequently grown in greenhouses for the sake of its perfume and flowers The leaves are not unlike those of the tobacco plant in shape but much more shiny and they exhale a strong smell like incense A leaf rubbed on my arm (left) a gummy secretion with a powerful smell and was followed by a bright red punctiform rash which lasted all day but caused little irritation. A gardener has told me that he has noticed his arms itching after moving the plants and that the gardener who gave them to him suffered from a severely inflamed face which was ascribed to an irritating soap but no doubt was due to the humea. It is well known that many plants like *Primula obconica* are irritants, but that *Humea elegans* is one of them was new to me and may be a warning to others

NOTE ON A CASE OF SPONTANEOUS REDUCTION OF ACUTE INTUSSUSCEPTION

By W Gifford Nash, F R.C S. Eng

A MALE child aged 11 months, between 12 and 1 o clock midday on June 4th was seized with abdominal pain which caused screaming and great collapse. Vomiting occurred. I was sent for and saw the child shortly before three o clock when I found him deathly pale and suffering from extreme collapse On examining the abdomen a swelling could be seen passing from the region of the cæcum obliquely upwards towards the epigastrium. On palpation a firm sausage-shaped tumour three or four inches in length could be felt. I concluded that an intussusception was present and made preparations for immediate operation Hot bottles were applied to the extremities and hot flannels to the abdomen. I saw the child again with my partner Dr. H. Savory at 4 o clock and found him looking much better having had a sleep. The lump could still be seen and felt, but was evidently smaller and during our manipulations it suddenly entirely disappeared. There was a history of looseness of the bowels on the previous evening

This appears to be a case in which spontaneous reduction *of an intussusception undoubtedly occurred.* I am perfectly certain that an intussusception was present. The symptoms of severe shock were very marked and the presence of a very distinct elongated tumour was very easy to demonstrate to the relatives. No doubt the diarrhœa of the previous night led up to the occurrence of the condition. The reasons why the intussusception was reduced appear to me to be three (1) the manipulations necessary to form a diagnosis acting on a very recent intussusception (2) the occurrence of faintness and vomiting leading to relaxation of muscular spasm and (3) the application of heat to the abdomen acting in the same way

ROYAL FREE HOSPITAL

A CASE OF EXPLORATION OF THE CEREBELLUM AND DRAINAGE OF A CEREBELLAR ABSCESS DURING ARTIFICIAL RESPIRATION

(Under the care of Mr E W ROUGHTON)

THE symptoms of cerebellar abscess when it is confined to a lateral lobe, are due only in part to the local damage to the cerebellar substance for it has been shown many times both by experiment and by disease that destruction of a very large part of a lateral lobe of the cerebellum usually gives rise to very few signs or symptoms, while injury of the middle lobe produces the characteristic disturbances of equilibrium. The greater part of the symptoms resulting from cerebellar abscess are caused by pressure on the foramen of Majendie which obstructs the outflow of cerebro-spinal fluid from the ventricles For the notes of the case we are indebted to Mr Joseph Cunning F R.C.S., senior resident medical officer

A boy aged 17 years, was admitted into the Royal Free Hospital under the care of Mr E. W Roughton on April 2nd 1902, complaining of frontal headache and pain behind the left ear The patient had had a discharge from both ears since an attack of scarlet fever 10 years ago Six days before admission he had received a ' box on the left ear and since then had had pain on the left side of the head and neck. He was able to work for three days but then he had to go to bed. Poultices were applied and the pain was relieved. On the fifth day he vomited each time after taking food and the pain became worse.

On admission the patient was very delicate, apathetic, very deaf, and quite intelligent though slow in cerebration The respirations were 17 the pulse was 48 and regular and the temperature was 99 2° F The urine was of specific gravity 1030 and contained no albumin, sugar pus, or blood There was tenderness over the left mastoid process and he complained of pain over the forehead the left side of the head and the back of the neck From both ears there was a foul smelling discharge. On the left side a quantity of thick epithelial débris was removed from the auditory canal and a perforation was seen in the membrane no bare bone was perceptible. On the right side a small polypoid mass of granulations protruded through a perforation in the membrane. The hearing was right $\frac{1}{26}$ and left $\frac{0}{26}$

The patient s condition continued to improve for eight days. His hearing became better the tenderness over the left mastoid process disappeared and generally he became brighter The pulse-rate rose to from 50 to 58 and he had no more vomiting but the headache though not so severe still continued. The temperature all this time remained at 98° Then the headache became worse and he vomited once daily for two days On the tenth day after admission he vomited four times. The temperature was 97° and the pulse was 58. His headache was worse. On the twelfth day the headache was very bad. He was still vomiting and now complained of giddiness. For the first time he was unable to lie on the right side as it increased the pain so much The left knee jerk was exaggerated there was no weakness or paralysis of either upper or lower extremities The pupils were equal and reacted to light, no squint or nystagmus being present. There were no fits or twitchings and there had been no delirium at any time Cerebellar abscess was diagnosed and as Mr Roughton was unable to come down he asked Mr Cunning to operate.

Owing to the severity of the headache Mr Cunning decided to shave the head and to prepare the scalp after the anæsthetic had been given. The left ear seemed to be the worse of the two and the tenderness when the patient was admitted to the hospital had been on the left side though it had now disappeared. The left knee jerk was also exaggerated In spite of that the inability to lie on the right side had been such a marked feature during the day that it was determined to attack the right side An injection of morphia (three minims) was given to minimise the amount of anæsthetic necessary Mr Sheffield Neave gave chloroform and it was noticed that after about half a drachm had been given the pulse increased in frequency to 120 After a drachm had been given the breathing ceased entirely while the corneal reflex remained. The heart went on beating As no attempt at spontaneous respiration occurred artificial respiration was begun the tongue being held well forward. The patient s colour remained good and artificial respiration was stopped to see if he would now breathe naturally but he only steadily became blue so artificial respiration was recommenced. As Mr Cunning felt convinced that this condition was due to pressure on the medulla inhibiting the respiratory centre it was determined to go on with the operation Having to prepare the scalp by scrubbing and shaving was the cause of a good deal of delay and during this time Silvester s method of artificial respiration could not be kept up In place of this Mr Neave knelt on the table and kept up alternate compression and relaxation of the thorax with his hands. As this was not nearly so efficient it was occasionally necessary to delay the operation and to resort to Silvester s method till the colour improved.

A flap of all the soft tissues was turned down over the right side of the occipital lobe to expose an area below the superior curved line and behind the posterior border of the mastoid process, and a piece of bone was removed with a three-quarter inch trephine. The opening was well clear of both the horizontal and the vertical portions of the lateral diet and by excretion into the bowel from the system, and that, on the other hand, uric acid and its compounds are excreted by the kidneys, and to a small extent by the skin, and separate out in those tissues in which the blood supply would appear to have a greater opportunity of depositing them than would be the case in the intestine. Sluggish action of the bowels is alleged as a cause of intestinal concretions, but this can only be a predisposing circumstance, for the milk diet and the sluggish state of the bowel do not alone appear to be able to bring about the condition of true intestinal sand All, then, that we can say at present is that the condition would appear to be very closely related to gout and to be favoured by a milk diet

ROYAL FREE HOSPITAL

A CASE OF EXPLORATION OF THE CEREBELLUM AND DRAINAGE OF A CEREBELLAR ABSCESS DURING ARTIFICIAL RESPIRATION

(Under the care of Mr E. W ROUGHTON)

THE symptoms of cerebellar abscess when it is confined to a lateral lobe, are due only in part to the local damage to the cerebellar substance for it has been shown many times both by experiment and by disease that destruction of a very large part of a lateral lobe of the cerebellum usually gives rise to very few signs or symptoms, while injury of the middle lobe produces the characteristic disturbances of equilibrium. The greater part of the symptoms resulting from cerebellar abscess are caused by pressure on the foramen of Majendie which obstructs the outflow of cerebro-spinal fluid from the ventricles. For the notes of the case we are indebted to Mr Joseph Cunning F R.C.S senior resident medical officer

A boy, aged 17 years was admitted into the Royal Free Hospital under the care of Mr. E. W Roughton on April 2nd, 1902, complaining of frontal headache and pain behind the left ear The patient had had a discharge from both ears since an attack of scarlet fever 10 years ago. Six days *before admission he had received a ' box on the left ear* and since then had had pain on the left side of the head and neck. He was able to work for three days but then he had to go to bed. Poultices were applied and the pain was relieved On the fifth day he vomited each time after taking food and the pain became worse.

On admission the patient was very delicate, apathetic, very deaf, and quite intelligent, though slow in cerebration. The respirations were 17 the pulse was 48 and regular and the temperature was 99 2° F The urine was of specific gravity 1030 and contained no albumin sugar pus, or blood There was tenderness over the left mastoid process and he complained of pain over the forehead the left side of the head and the back of the neck From both ears there was a foul smelling discharge. On the left side a quantity of thick epithelial débris was removed from the auditory canal and a perforation was seen in the membrane no bare bone was perceptible. On the right side a small polypoid mass of granulations protruded through a perforation in the membrane *The hearing was right* $\frac{1}{26}$ *and left* $\frac{0}{26}$

The patient s condition continued to improve for eight days. His hearing became better the tenderness over the left mastoid process disappeared and generally he became brighter The pulse-rate rose to from 50 to 58 and he had no more vomiting but the headache though not so severe still continued. The temperature all this time remained at 98° Then the headache became worse and he vomited once daily for two days On the tenth day after admission he vomited four times. The temperature was 97° and the pulse was 58. His headache was worse. On the twelfth day the headache was very bad He was still vomiting and now complained of giddiness. For the first time he was unable to lie on the right side as it increased the pain so much. The left knee-jerk was exaggerated; there was no weakness or paralysis of either upper or lower extremities The pupils were equal and reacted to light, no squint or nystagmus being present. There were no fits or twitchings and there had been no delirium at any time Cerebellar abscess was *diagnosed and as Mr Roughton was unable to come down he* asked Mr Cunning to operate.

Owing to the severity of the headache Mr Cunning decided to shave the head and to prepare the scalp after the anæsthetic had been given. The left ear seemed to be the worse of the two and the tenderness when the patient was admitted to the hospital had been on the left side, though it had now disappeared. The left knee jerk was also exaggerated In spite of that the inability to lie on the right side had been such a marked feature during the day that it was determined to attack the right side An injection of morphia (three minims) was given to minimise the amount of anæsthetic necessary Mr Sheffield Neave gave chloroform and it was noticed that after about half a drachm had been given the pulse increased in frequency to 120 After a drachm had been given the breathing ceased entirely while the corneal reflex remained The heart went on beating As no attempt at spontaneous respiration occurred artificial respiration was begun the tongue being held well forward. The patient s colour remained *good and artificial respiration was stopped to see* if he would now breathe naturally but he only steadily became blue, so artificial respiration was recommenced. As Mr Cunning felt convinced that this condition was due to pressure on the medulla inhibiting the respiratory centre it was determined to go on with the operation. Having to prepare the scalp by scrubbing and shaving was the cause of a good deal of delay and during this time Silvester s method of artificial respiration could not be kept up In place of this Mr Neave knelt on the table and kept up alternate compression and relaxation of the thorax with his hands As this was not nearly so efficient it was occasionally necessary to delay the operation and to resort to Silvester s method till the colour improved

A flap of all the soft tissues was turned down over the right side of the occipital lobe to expose an area below the superior curved line and behind the posterior border of the mastoid process, and a piece of bone was removed with a three-quarter inch trephine. The opening was well clear of both *the horizontal* and the vertical portions of the lateral diet and by excretion into the bowel from the system, and that, on the other hand, uric acid and its compounds are excreted by the kidneys, and to a small extent by the skin, and separate out in those tissues in which the blood supply would appear to have a greater opportunity of depositing them than would be the case in the intestine. Sluggish action of the bowels is alleged as a cause of intestinal concretions, but this can only be a predisposing circumstance, for the milk diet and the sluggish state of the bowel do not alone appear to be able to bring about the condition of true intestinal sand. All, then, that we can say at present is that the condition would appear to be very closely related to gout and to be favoured by a milk diet.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

NOTE ON A CASE OF SPRUE

BY R. MUZIO WILLIAMS, M.D. LOND.,

AND

M. H. SPENCER, M.D. CANTAB.

WE thought that the following short account of this case might be of interest, more especially as the diagnosis of sprue appears still to be frequently missed, for though the patient had evidently had the disease for some time and had seen at least eight or nine medical men it had never been even suggested as being sprue.

The patient, a woman aged 42 years, came into a home on May 4th last, having landed from India on the same morning. The only serious illness she had had previously to the present one was an attack of severe diarrhœa 10 years ago which lasted for some months and necessitated her return home from India where she was then residing. During the last four years she had suffered from intermittent diarrhœa, with increasing weakness and emaciation, at times, however, partially recovering for a period and regaining some of the weight which she had lost. The stools were not very frequent—generally only four or five daily—semi-solid, fermenting in character, and of a light yellowish grey colour. She had complained of a sore condition of the mouth and tongue for some time. In spite of periods of intermission the disease progressed insidiously, and at the time of her return to England she was exceedingly emaciated and in a very feeble condition. During the last month, whilst on her voyage home, the bowels were somewhat constipated and enemata were generally necessary to secure an action.

On admission she was extremely emaciated and profoundly anæmic. The skin was drawn tightly over the face and bony points of the body and was pigmented of a dirty brown colour, the pigmentation being specially marked on the neck and face. The pulse was feeble, 92, and the temperature was subnormal, only on one occasion reaching 98.4° F. The slightest movement caused syncopic attacks. The heart was not enlarged. There were loud blowing murmurs with systole and diastole over the apical region not conducted into the axilla. The spleen was not felt. The liver was felt for two fingerbreadths below the costal margin and the upper margin of dulness commenced at the sixth interspace. The urine contained a trace of albumin. Dr. Patrick Manson kindly examined the blood and reported as follows: "The blood is that of simple anæmia, a few poikilocytes present but nothing like pernicious anæmia." The tongue was white and glazed and completely denuded of epithelium, the buccal mucous membrane was in a similar condition, and there were two small ulcers near the anterior pillars of the fauces. The conjunctivæ were pearly white. She took nourishment fairly well. The following day, after consultation with Dr. Manson, as her pulse was rapidly becoming worse she was infused by Mr. Abbott with two pints of normal saline solution containing one-tenth of a grain of strychnine sulphate and three drachms of brandy. After this her pulse improved a good deal and she expressed herself as feeling much better. Two hours later, however, she had another syncopic attack and died.

A post-mortem examination was made by us 20 hours after death. The body was extremely emaciated, there being hardly a trace of fat left in the tissues. The lungs were entirely free from adhesions, crepitant throughout, but markedly bloodless; there was no trace of tuberculous deposit present in them. There was a small quantity of clear fluid in the left pleural cavity. The heart was somewhat atrophied but, contrary to expectation, the ventricular walls did not show any marked attenuation. There was no naked-eye appearance of degenerative change in the muscle or endocardium; the valves were competent and healthy. The liver, unlike what is generally found in these cases, was somewhat enlarged, greasy and fatty, easily breaking down on pressure with the thumb. The pancreas was firm and rather tough on section, suggesting some fibrotic change. This has been noted in other cases reported. The spleen was small, firm, and pale. The kidneys were firm and markedly anæmic, the capsule peeled readily, and the surface was not granular. The whole intestinal tract from the duodenum to the rectum was extraordinarily thinned. The bowel contained a quantity of slimy mucus. On washing this away the mucous membrane was found to be practically absent. In the small intestine and cæcum the bowel wall was so thinned as to be transparent when held up to the light and so friable as to tear very readily on handling. This diaphanous condition of the bowel was marked through its whole extent but most noticeable in the small intestine and cæcum. In places there were small diverticula formed owing to the extreme attenuation of the walls. They were of about the size of a walnut and could hardly be touched without tearing. The omentum contained scarcely any fat. There was no enlargement of the mesenteric glands. The stomach was dilated and full of undigested fluid; it was thin walled and perfectly white. There was no ulceration present in any part of the alimentary tract. The pelvic organs were normal with the exception of two small parovarian cysts and there was no sign of previous peritonitis.

A CASE OF DERMATITIS CAUSED BY HUMEA ELEGANS

BY WALTER CARRINGTON HEARNDEN, M.R.C.S. ENG.

THE following case may be of interest to some of the readers of THE LANCET as it illustrates the difficulty of fixing the cause of certain skin eruptions.

A female patient of mine who has a particularly delicate complexion, has during the last few months been frequently suffering from vesicular eruptions on the nose and cheeks looking like impetigo. They quickly subsided under treatment but as there was an almost immediate relapse she consulted a specialist who diagnosed eczema and naturally ordered a course of arsenic. On June 7th I found her with a red, swollen face, the left eye closed, large vesicles containing clear serum on the cheeks, and a patch of eczema on the left side of the chin. She was greatly alarmed as she supposed that she had erysipelas. Her temperature, however, was normal. She was unable to account for the attack, but first noticed it after playing ping pong. She had not been handling *Primula obconica* as she was aware of its dangers, but she volunteered the statements that she had been feeding chickens with crushed bones and that she had noticed some irritation about the nose. The attack subsided in the course of a few days under lotio plumbi subacetatis. The first time she went out, at the end of the week when her face was well, she complained of itching of her right eyelid and in the course of a few hours her face was as bad as ever. She then said that she had picked a leaf of *Humea elegans*, and had smelt it and that she had been in the habit during the last few months of picking a leaf and rubbing it on her veil as she liked the perfume. The position of the rash was just where a veil would touch the face and the patch on the chin corresponded to the place where the veil is screwed up and tucked in. No doubt this had been the cause of all the trouble.

Humea elegans, a native of New South Wales, is frequently grown in greenhouses for the sake of its perfume and flowers. The leaves are not unlike those of the tobacco plant in shape but much more shiny and they exhale a strong smell like incense. A leaf rubbed on my arm [left] a gummy secretion with a powerful smell and was followed by a bright red punctiform rash which lasted all day but caused little irritation. A gardener has told me that he has noticed his arms itching after moving the plants and that the gardener who gave them to him suffered from a severely inflamed face which was ascribed to an irritating soap but no doubt was due to the humea. It is well known that many plants like *Primula obconica* are irritants, but that *Humea elegans* is one of them was new to me and may be a warning to others

Leatherhead

NOTE ON A CASE OF SPONTANEOUS REDUCTION OF ACUTE INTUSSUSCEPTION

By W GIFFORD NASH, F R.C S. Eng

A MALE child aged 11 months, between 12 and 1 o clock midday *on June 4th was seized with abdominal pain* which caused screaming and great collapse. Vomiting occurred. I was sent for and saw the child shortly before three o clock when I found him deathly pale and suffering from extreme collapse On examining the abdomen a swelling could be seen passing from the region of the cæcum obliquely upwards towards the epigastrium. On palpation a firm sausage-shaped tumour three or four inches in length could be felt. I concluded that an intussusception was present and made preparations for immediate operation Hot bottles were applied to the extremities and hot flannels to the abdomen. I saw the child again with my partner Dr. H. Savory at 4 o clock and found him looking much better having had a sleep The lump could still be seen and felt, but was evidently smaller and during our manipulations it *suddenly entirely disappeared. There was a history* of looseness of the bowels on the previous evening

This appears to be a case in which spontaneous reduction of an intussusception undoubtedly occurred. I am perfectly certain that an intussusception was present. The symptoms of severe shock were very marked and the presence of a very distinct elongated tumour was very easy to demonstrate to the relatives. No doubt the diarrhœa of the previous night led up to the occurrence of the condition. The reasons why the intussusception was reduced appear to me to be three (1) the manipulations necessary to form a diagnosis acting on a very recent intussusception (2) the occurrence of faintness and vomiting leading to relaxation of muscular spasm and (3) the application of heat to the abdomen acting in the same way

HOSPITAL PRACTICE,

BRITISH AND FOREIGN

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.* lib. iv Proœmium.

ROYAL FREE HOSPITAL.

A CASE OF EXPLORATION OF THE CEREBELLUM AND DRAINAGE OF A CEREBELLAR ABSCESS DURING ARTIFICIAL RESPIRATION

(Under the care of Mr E. W ROUGHTON)

THE symptoms of cerebellar abscess, when it is confined to a lateral lobe, are due only in part to the local damage to the cerebellar substance for it has been shown many times both by experiment and by disease that destruction of a very large part of a lateral lobe of the cerebellum usually gives rise to very few signs or symptom while injury of the middle lobe produces the characteristic disturbances of equilibrium. The greater part of the symptoms resulting from cerebellar abscess are caused by pressure on the foramen of Majendie which obstructs the outflow of cerebro-spinal fluid from the ventricles For the notes of the case we are indebted to Mr Joseph Cunning F R.C.S. senior resident medical officer

A boy, aged 17 years, was admitted into the Royal Free Hospital under the care of Mr E. W Roughton on April 2nd 1902, complaining of frontal headache and pain behind the left ear The patient had had a discharge from both ears since an attack of scarlet fever 10 years ago Six days before admission he had received a "box" on the left ear and since then had had pain on the left side of the head and neck He was able to work for three days but then he had to go to bed. Poultices were applied and the pain was relieved. On the fifth day he vomited each time after taking food and the pain became worse.

On admission the patient was very delicate, apathetic, very deaf, and quite intelligent though slow in cerebration. The respirations were 17 the pulse was 48 and regular and the temperature was 99·2° F The urine was of specific gravity 1030 and contained no albumin, sugar pus, or blood There was tenderness over the left mastoid process and he complained of pain over the forehead the left side of the head and the back of the neck From both ears there was a foul smelling discharge. On the left side a quantity of thick epithelial débris was removed from the auditory canal and a perforation was seen in the membrane no bare bone was perceptible. On the right side a small polypoid mass of granulations protruded through a perforation in the membrane. The hearing was right $\frac{1}{26}$ and left $\frac{0}{26}$

The patient s condition continued to improve for eight days. His hearing became better the tenderness over the left mastoid process disappeared, and generally he became brighter The pulse-rate rose to from 50 to 58 and he had no more vomiting but the headache though not so severe still continued The temperature all this time remained at 98° Then the headache became worse and he vomited once daily for two days On the tenth day after admission he vomited four times The temperature was 97° and the pulse was 58. His headache was worse. On the twelfth day the headache was very bad. He was still vomiting and now complained of giddiness. For the first time he was unable to lie on the right side as it increased the pain so much The left knee jerk was exaggerated, there was no weakness or paralysis of either upper or lower extremities The pupils were equal and reacted to light, no squint or nystagmus being present. There were no fits or twitchings and there had been no delirium at any time Cerebellar abscess was diagnosed and as Mr Roughton was unable to come down he asked Mr Cunning to operate.

Owing to the severity of the headache Mr Cunning decided to shave the head and to prepare the scalp after the anæsthetic had been given The left ear seemed to be the worse of the two and the tenderness when the patient was admitted to the hospital had been on the left side though it had now disappeared. The left knee jerk was also exaggerated. In spite of that the inability to lie on the right side had been such a marked feature during the day that it was determined to attack the right side An injection of morphia (three minims) was given to minimise the amount of anæsthetic necessary Mr Sheffield Neave gave chloroform and it was noticed that after about half a drachm had been given the pulse increased in frequency to 120 After a drachm had been given the breathing ceased entirely while the corneal reflex remained. The heart went on beating As no attempt at spontaneous respiration occurred artificial respiration was begun the tongue being held well forward. The patient s colour remained good and artificial respiration was stopped to see if he would now breathe naturally but he only steadily became blue, so artificial respiration was recommenced. As Mr Cunning felt convinced that this condition was due to pressure on the medulla inhibiting the respiratory centre it was determined to go on with the operation. Having to prepare the scalp by scrubbing and shaving was the cause of a good deal of delay and during this time Silvester s method of artificial respiration could not be kept up In place of this Mr Neave knelt on the table and kept up alternate compression and relaxation of the thorax with his hands As this was not nearly so efficient it was occasionally necessary to delay the operation and to resort to Silvester s method till the colour improved

A flap of all the soft tissues was turned down over the right side of the occipital lobe to expose an area below the superior curved line and behind the posterior border of the mastoid process, and a piece of bone was removed with a three-quarter inch trephine. The opening was well clear of both the horizontal and the vertical portions of the lateral hæmorrhage might be external or internal. In the external if the uterine contractions were active then the membranes should be ruptured and the uterus massaged or a tight binder applied. If the bleeding continued then the uterus should be emptied as soon as possible by turning or by forceps Dr Jardine referred to the Rotunda method of plugging and the reasons adduced for its use, but he could not agree with their theory In these cases the uterine wall was not in a normal condition If strong contractions were occurring then plugging might be used, but if there were no contractions then there would be great risk of converting an external into an internal hæmorrhage He had seen one case in which this happened with fatal result If the hæmorrhage was severe the uterus should be emptied as quickly as possible, the os being dilated by hand or by a Champetier de Ribes bag As soon as the child was born the hand should be inserted into the uterus and the placenta and clots should be removed Ergotin should be given and the uterus plugged if post partum hæmorrhage was occurring The plug could be wrung out of suprarenal extract solution A saline infusion should be given if much blood had been lost or if there had been much shock. Concealed internal hæmorrhage was the most fatal of all the forms Rupturing the membranes would only make more room for blood to be poured out, and delivery by accouchement forcé was not very hopeful if the hæmorrhage was severe In Dr Jardine's experience of many cases such treatment was disastrous. He favoured removal of the uterus by Porro's operation A helpful symptom in diagnosing this condition was that the patient complained of severe pain of a continuous character in the abdomen If the condition was recognised early then the membranes should be ruptured before there was sufficient bleeding to cause collapse Another source of hæmorrhage in the early stage of labour might be a commencing spontaneous rupture of the uterus, but it could not be diagnosed till the rupture had occurred, when abdominal section and removal of the uterus should be carried out.

After Dr Robert Barnes (London) had made some remarks on the use of bags as dilators,

Professor A. R. Simpson referred to the pleasure that the societies had in hearing the Nestor of British midwifery open the discussion He referred to the carelessness of women suffering from hæmorrhage. Many of the subjects of placenta prævia suffered previously from endometritis and thus were accustomed to considerable losses of blood, so that the hæmorrhage during pregnancy did not alarm them. He believed in palliative treatment at first, warning the patient to give immediate intimation of any recurrence, if this should occur the active interference should be at once carried out The worst and most fatal cases were those where there had been repeated hæmorrhages and where only a little was sufficient at last to cause death

Dr J M Munro Kerr (Glasgow) referred to his experience in 10 cases He considered it important to diagnose the variety and apply the treatment accordingly

Dr D Berry Hart considered that the best treatment if the hæmorrhage was severe was to dilate the os rapidly till it would admit two or three fingers, then to perform bipolar version, bring down a foot, and allow the case aftewards to be terminated naturally By doing this they would save more children than if they hastened the termination of the labour

Professor J A. C Kynoch (Dundee) considered that the treatment mainly resolved itself into that by bipolar version. The os must be dilated to permit of this being carried out and this could be accomplished by packing or by the use of bags, but he had never required to use these, having always attained this object by digital dilatation Careful attention should be given to asepsis in all the procedure, as these cases had a special tendency to sepsis He considered rapid delivery to be disastrous

Dr J Haig Ferguson did not consider Porro's operation or Cæsarean section necessary in any case of accidental hæmorrhage If labour had commenced in such a case he ruptured the membranes and left to nature, applying forceps or turning if afterwards required

Dr J C Herbertson (Glasgow) considered that the treatment had to be modified according to the position of the patient, as if she were of the working class she could not lie in bed for a long period and she would increase the danger by getting up Such a case would require interference, whereas another in better circumstances would only necessitate watching

Dr F W N Haultain remarked that the discussion had revealed a lamentable state of obstetric nomenclature, as was evidenced by the use of the terms "overlapping," "partial," "lateral," &c., for the same condition of placenta If the hæmorrhage was not urgent he gave the patient the benefit of the doubt and used palliative measures, but he warned the patient of the risk. He considered that the patient should be informed of the condition and be allowed to decide for herself whether she cared to run the risk Those of the patients who died did so from post-partum hæmorrhage and this often consisted in a steady ooze of blood which pressure and the hot douche would not stop Plugging was the only method to stop it, and yet there were text-books which taught students not to do so in post-partum hæmorrhage He supported the treatment of concealed accidental hæmorrhage by abdominal operation

Dr Alexander Miller (Glasgow) had no faith in palliative measures, if the hæmorrhage were severe and the patient near full time he administered chloroform, used digital dilatation, performed podalic version, and delivered the child as soon as possible The sooner the uterus was emptied the better

Dr Michael Dewar stated that he had only met three cases of placenta prævia in 2000 cases attended in practice. The great point with a practitioner was to distinguish between accidental and unavoidable, and this was not always easy, especially if the os was not dilated and the blood was escaping in considerable gushes

Dr S MacVie (Chirnside) said that country practitioners considered these cases from a different point of view, there was no cut-and dry system for them He did not put the decision of the treatment to the mother but kept her in the dark so as not to put her into an alarming state of nervous excitement He first palpated the uterus carefully to locate the placenta if possible, as this helped subsequent treatment very much He dilated the os by the fingers and turned till he got hold of a foot, this when pulled down might stop external bleeding but yet some internal hæmorrhage might be occurring and he felt more satisfied when the body was down He alluded to the tight packing that had been recommended during the discussion and advised caution, as a neighbour of his had plugged the vagina so tightly in one case as to cause sloughing

The President referred to the general opinion in favour of plugging in post-partum hæmorrhage Statistics of the frequency of placenta prævia differed very much and this affected the mortality percentage. He believed that many cases of marginal placenta prævia were overlooked in private practice The diagnosis of placenta prævia from the examination of the after birth by measuring the distance between the rupture in the membranes and the edge of the placenta was not trustworthy

Dr Jardine, in reply, referred to several cases of placenta prævia which had a previous history of endometritis or curetting and there was probably a causal relation He always carried out antiseptic treatment very carefully He thought that a mortality of 23 per cent. was too high, of 150 cases in the Glasgow Maternity he found that the death rate was 5 per cent. in more recent years and 17 per cent. previously, so that the advance in treatment had influenced the mortality These cases were often admitted moribund into hospital and swelled the mortality He adhered to his opinion in advising Porro's operation in cases of serious concealed hæmorrhage There might be placenta prævia cases converted into concealed by internal hæmorrhage, but whatever the cause if the uterus was so dilated that the walls seemed ready to burst he considered operation to be the woman's best chance. He had not yet operated in such a case but he intended doing so in the next one as in all such cases which he had met the patients had died under other treatment

Dr A. W Russell and Dr G Balfour Marshall (Glasgow) also joined in the discussion

The Fellows afterwards dined together

British Laryngological, Rhinological, and Otological Association —A meeting of this society was held on July 11th, Dr J Macintyre, the President, being in the chair —Dr V H. Wyatt Wingrave read notes of a case of Bilateral Adductor Paralysis in a boy, aged 7 years —Mr Lennox Browne inquired if adenoids were present or if there was any symptom pointing to reflex disturbance —Dr J Dundas Grant said that he had seen the patient and had found the larynx to be normal in every respect. He regarded the case as one of hysterical aphonia.—Mr E. Dennis Vinrace asked if there had been a tendency to relapse.—Dr Wingrave, replying said that he had removed adenoids. One application of the interrupted current quickly restored the voice.—Mr Lennox Browne read notes of a case of Keratosis of the Tonsils without Leptothrix in a young adult. He had removed the tonsils of which Dr Wingrave now showed microscopical sections.—Dr Wingrave described two varieties of Tonsillar Keratosis, one in which the horny growth projected through the open mouth of the crypt, the other where the orifice being closed the horny epithelium formed a perle" in the lacuna.—Dr Grant remarked that the condition was apt to disappear without apparent cause.—After some observations by Mr W J Chichele Nourse, Dr W Jobson Horne, and the President, Mr Lennox Browne and Dr Wingrave replied.—Dr W H Kelson showed a case of Tuberculous Tracheitis. The patient, whose two brothers died from phthisis had congestion of the larynx and ulceration at the upper and anterior part of the trachea. The sputa contained quantities of tubercle bacilli.—Dr Kelson also read notes of a case of Singer's Nodes on both Cords in a choir boy —Dr Grant showed a case of Congenital Papillomata of the Larynx in a female, aged 23 years who had worn a tracheotomy tube from infancy until the time that she consulted him four weeks ago Her voice then resembled that of functional aphonia. The lips and tongue moved but there was no phonation Dr Grant removed the papillomata with forceps and snare and cleared the larynx, so that the patient was able to breathe through the natural channel Later he closed the tracheal wound. The patient had now a fair voice.—Mr Lennox Browne congratulated Dr Grant upon the result. The patient, who was before voiceless, could now utter a good vowel sound He could recall only one similar case. *In that instance it was some time after the removal of* the papillomata before the patient was able to speak —Dr Kelson pointed out that the case was evidence in support of the view that tracheotomy alone was not curative in cases of papillomata of the larynx.—After a few remarks by the President Dr Grant replied.—Dr Grant also showed a Bent Glass Tube of a useful form devised by Dr. Leduc of Nantes for enabling a patient to apply remedies in the form of powder to his own larynx —The President showed 1. Photographs of the new electrical department at the Glasgow Royal Infirmary Besides apparatus for x rays and high frequency currents and a very large static machine there was a huge and very powerful electro-magnet for removing foreign bodies from the trachea, &c. 2. Photographs of a case of Cancer of the Nose in a woman aged 60 years Two months ago an old wart took on a very rapid growth. On removal of the external mass it was found to have penetrated the cartilage and to be invading the tissues inside the nose The case was now under treatment by the x rays

Anatomical Society of Great Britain and Ireland —The summer meeting of this society was held at St. Bartholomew's Hospital Medical School on July 3rd and 4th, Mr C B Lockwood the President, being in the chair The meeting which was well attended both by the London and provincial members commenced each day at 3 P.M. Amongst the visitors present was Professor Fürst of Lund, Sweden. The following communications were brought before the notice of the society —Dissections of Two Twin Monsters with lantern illustrations and specimens by Dr R. J A. Berry (Edinburgh) Flexor Carpi Radialis of an Elephant showing Great Development of Elastic Tissue, by Mr R. H. Burne a specimen showing a Band formed by a Persistent Vitelline Artery by Mr R. C. Bailey Two Hearts showing peculiarities of the Great Veins, by Dr D N Nabarro the Relations of the Deeper Parts of the Brain to the Surface, illustrated by specimens, photographs and lantern slides by Professor J Symington (Belfast) a lantern demonstration on the Extent to which Lumbar Segments of the Body have been transmuted to Sacral in the Evolution of Man and the Higher Primates by Dr Arthur Keith Vestigial First Rib by Professor Macphail (Glasgow) a Minimal Form of Fissura Facialis by Mr N B Harman Some Points on the Topographical Anatomy of the Thoracic and Abdominal Viscera in Hylobates Hainanus by Professor C J Patten (Sheffield) exhibition of the Skull and other Bones from a case of Acromegaly by Professor A F Dixon (Cardiff), a preliminary communication on the Development of the Pericardium by Professor Arthur Robinson the Sternal Angle in Man by Dr Walter Kidd the Form of the Human Spleen, by Mr R. K. Shepherd (Cardiff) On the morning of July 3rd the members and visitors made a formal visit to the museum of the Royal College of Surgeons of England to view the new museum specimens Mr R. H Burne kindly received them and showed the recent additions which had been made to the museum In the evening the annual dinner was held at the Café Royal Regent-street, and was attended by upwards of 40 members and guests. Amongst the latter were Sir W S Church Mr A. Willett Mr H. T Butlin Professor Haddon Mr F G Hallett, Dr J Calvert, and Professor Fürst. The dinner was one of the most successful that has been held by the society Through the kindness of the officers of the Zoological Society of London arrangements were made for a visit to the Zoological Gardens, Regent's Park on the morning of July 4th, when the members of the society had the special advantage of being accompanied by Mr Frank Beddard F R.S After a tour of the gardens had been made the provincial members and guests were entertained at luncheon by the London members of the society In the evening the President entertained the provincial members at dinner

Dermatological Society of Great Britain and Ireland —A meeting of this society was held on July 16th Dr J H. Stowers the President, being in the chair —Dr A. Eddowes showed (1) a case of Dysidrosis in the form of Erythema Exudativum (a private patient) and (2) a case of Bullous Eruption.—Dr T D Savill showed a case of Hebra's Prurigo —Dr E. G Graham Little showed (1) a Case for Diagnosis (2) a case of Acne Scrofulosorum and (3) a case of Lichen Hypertrophicus with extensive lesions of the mucous membrane of the mouth —The President showed cases of (1) Lupus (2) Lupus Erythematosus and (3) Alopecia.—Dr E Stainer showed (1) a Girl aged 12 years with Linear Papilloma of the Arm, and (2) Tuberculide Eruption on the legs of a boy aged nine years.—At the annual meeting the following officers were elected —President Dr Stowers. President-elect Dr H. Waldo Vice-Presidents Dr P S. Abraham, Dr. R. L. Bowles, Sir Alfred Cooper Dr H. Radcliffe Crocker Sir G F Duffey Dr James Galloway Dr A. J Harrison J P Dr Robert Liveing and Dr H. H. Phillips-Conn. Treasurer Dr W T Freeman. Council Dr W Beatty Dr H A. G Brooke, Dr A. Eddowes Dr A. J Hall Mr T J Hitchins, Dr Graham Little Mr George Pernet, Dr Leslie Roberts, Mr G W Sequeira, Dr R. Travers Smith Dr Stainer and Dr C H. Thompson Secretaries Mr Arthur Shillitoe and Dr Wilfrid B Warde.

Ophthalmic Myology A Systematic Treatise on the Ocular Muscles By G C. Savage, M.D Professor of Ophthalmology in the Medical Department of Vanderbilt University Nashville, Tennessee Published by the Author 1902. Crown 8vo Pp 589

The study of the actions of the extrinsic muscles of the eye has been pursued of late years with remarkable energy and enthusiasm by the Americans and the writings of Stevens Duane Swan Burnett, H. Wilson, Culbertson Reber and many others have done much to elucidate our knowledge of these muscles and to explain the consequences of their excessive and of their defective power the appreciation of which has an important bearing on treatment. About the middle of the last century it was customary to perform a tenotomy upon almost every case of squint that appeared amongst the out patients of a hospital and though doubtless many cases proved fairly successful there were others in which the results were disastrous the patient leaving the hospital with a disfigurement greater than that from which he had expected to be relieved. In course of time the study of the refraction of the eyes of the form of the globe of the pathological conditions in the interior of the eye as well as of the extrinsic neuro-muscular apparatus, aided by considerable improvements in the methods of operation has materially assisted the surgeon in selecting appropriate cases hæmorrhage might be external or internal. In the external if the uterine contractions were active then the membranes should be ruptured and the uterus massaged or a tight binder applied. If the bleeding continued then the uterus should be emptied as soon as possible by turning or by forceps Dr Jardine referred to the Rotunda method of plugging and the reasons adduced for its use, but he could not agree with their theory In these cases the uterine wall was not in a normal condition. If strong contractions were occurring then plugging might be used, but if there were no contractions then there would be great risk of converting an external into an internal hæmorrhage He had seen one case in which this happened with fatal result. If the hæmorrhage was severe the uterus should be emptied as quickly as possible, the os being dilated by hand or by a Champetier de Ribes bag As soon as the child was born the hand should be inserted into the uterus and the placenta and clots should be removed Ergotin should be given and the uterus plugged if post-partum hæmorrhage was occurring The plug could be wrung out of suprarenal extract solution A saline infusion should be given if much blood had been lost or if there had been much shock. Concealed internal hæmorrhage was the most fatal of all the forms Rupturing the membranes would only make more room for blood to be poured out, and delivery by accouchement forcé was not very hopeful if the hæmorrhage was severe. In Dr Jardine's experience of many cases such treatment was disastrous He favoured removal of the uterus by Porro's operation. A helpful symptom in diagnosing this condition was that the patient complained of severe pain of a continuous character in the abdomen. If the condition was recognised early then the membranes should be ruptured before there was sufficient bleeding to cause collapse Another source of hæmorrhage in the early stage of labour might be a commencing spontaneous rupture of the uterus, but it could not be diagnosed till the rupture had occurred, when abdominal section and removal of the uterus should be carried out.

After Dr ROBERT BARNES (London) had made some remarks on the use of bags as dilators,

Professor A. R. SIMPSON referred to the pleasure that the societies had in hearing the Nestor of British midwifery open the discussion. He referred to the carelessness of women suffering from hæmorrhage. Many of the subjects of placenta prævia suffered previously from endometritis and thus were accustomed to considerable losses of blood, so that the hæmorrhage during pregnancy did not alarm them. He believed in palliative treatment at first, warning the patient to give immediate intimation of any recurrence, if this should occur the active interference should be at once carried out The worst and most fatal cases were those where there had been repeated hæmorrhages and where only a little was sufficient at last to cause death.

Dr J M MUNRO KERR (Glasgow) referred to his experience in 10 cases He considered it important to diagnose the variety and apply the treatment accordingly

Dr D BERRY HART considered that the best treatment if the hæmorrhage was severe was to dilate the os rapidly till it would admit two or three fingers, then to perform bipolar version, bring down a foot, and allow the case aftewards to be terminated naturally By doing this they would save more children than if they hastened the termination of the labour

Professor J A. C KYNOCH (Dundee) considered that the treatment mainly resolved itself into that by bipolar version. The os must be dilated to permit of this being carried out and this could be accomplished by packing or by the use of bags, but he had never required to use these, having always attained this object by digital dilatation. Careful attention should be given to asepsis in all the procedure, as these cases had a special tendency to sepsis. He considered rapid delivery to be disastrous

Dr J HAIG FERGUSON did not consider Porro's operation or Cæsarean section necessary in any case of accidental hæmorrhage If labour had commenced in such a case he ruptured the membranes and left to nature, applying forceps or turning if afterwards required

Dr J C HERBERTSON (Glasgow) considered that the treatment had to be modified according to the position of the patient, as if she were of the working class she could not lie in bed for a long period and she would increase the danger by getting up Such a case would require interference, whereas another in better circumstances would only necessitate watching

Dr F W N HAULTAIN remarked [illegible] the discussion had revealed a lamentable state of obstetric nomenclature, as was evidenced by the use of the terms "overlapping," "partial," "lateral," &c, for the same condition of placenta. If the hæmorrhage was not urgent he gave the patient the benefit of the doubt and used palliative measures, but he warned the patient of the risk. He considered that the patient should be informed of the condition and be allowed to decide for herself whether she cared to run the risk Those of the patients who died did so from post-partum hæmorrhage and this often consisted in a steady ooze of blood which pressure and the hot douche would not stop Plugging was the only method to stop it, and yet there were text-books which taught students not to do so in post-partum hæmorrhage He supported the treatment of concealed accidental hæmorrhage by abdominal operation

Dr ALEXANDER MILLER (Glasgow) had no faith in palliative measures, if the hæmorrhage were severe and the patient near full time he administered chloroform, used digital dilatation, performed podalic version, and delivered the child as soon as possible The sooner the uterus was emptied the better

Dr MICHAEL DEWAR stated that he had only met three cases of placenta prævia in 2000 cases attended in practice. The great point with a practitioner was to distinguish between accidental and unavoidable, and this was not always easy, especially if the os was not dilated and the blood was escaping in considerable gushes

Dr S MACVIE (Chirnside) said that country practitioners considered these cases from a different point of view, there was no cut-and dry system for them He did not put the decision of the treatment to the mother but kept her in the dark so as not to put her into an alarming state of nervous excitement. He first palpated the uterus carefully to locate the placenta if possible, as this helped subsequent treatment very much. He dilated the os by the fingers and turned till he got hold of a foot, this when pulled down might stop external bleeding but yet some internal hæmorrhage might be occurring and he felt more satisfied when the body was down. He alluded to the tight packing that had been recommended during the discussion and advised caution, as a neighbour of his had plugged the vagina so tightly in one case as to cause sloughing

The PRESIDENT referred to the general opinion in favour of plugging in post-partum hæmorrhage Statistics of the frequency of placenta prævia differed very much and this affected the mortality percentage. He believed that many cases of marginal placenta prævia were overlooked in private practice. The diagnosis of placenta prævia from the examination of the after birth by measuring the distance between the rupture in the membranes and the edge of the placenta was not trustworthy

Dr JARDINE, in reply, referred to several cases of placenta prævia which had a previous history of endometritis or curetting and there was probably a causal relation He always carried out antiseptic treatment very carefully He thought that a mortality of 23 per cent. was too high, of 150 cases in the Glasgow Maternity he found that the death-rate was 5 per cent. in more recent years and 17 per cent. previously, so that the advance in treatment had influenced the mortality These cases were often admitted moribund into hospital and swelled the mortality He adhered to his opinion in advising Porro's operation in cases of serious concealed hæmorrhage There might be placenta prævia cases converted into concealed by internal hæmorrhage, but whatever the cause if the uterus was so dilated that the walls seemed ready to burst he considered operation to be the woman's best chance. He had not yet operated in such a case but he intended doing so in the next one as in all such cases which he had met the patients had died under other treatment

Dr A. W RUSSELL and Dr G BALFOUR MARSHALL (Glasgow) also joined in the discussion

The Fellows afterwards dined together

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION —A meeting of this society was held on July 11th, Dr J Macintyre, the President, being in the chair —Dr V H Wyatt Wingrave read notes of a case of Bilateral Adductor Paralysis in a boy, aged 7 years —Mr Lennox Browne inquired if adenoids were present or if there was any symptom pointing to reflex disturbance.—Dr J Dundas Grant said that he had seen the patient and had found the larynx to be normal in every respect. He regarded the case as one of hysterical aphonia.—Mr E. Dennis Vinrace asked if there had been a tendency to relapse.—Dr Wingrave, replying said that he had removed adenoids. One application of the interrupted current quickly restored the voice.—Mr Lennox Browne read notes of a case of Keratosis of the Tonsils without Leptothrix in a young adult. He had removed the tonsils, of which Dr Wingrave now showed microscopical sections.—Dr Wingrave described two varieties of Tonsillar Keratosis, one in which the horny growth projected through the open mouth of the crypt, the other where, the orifice being closed, the horny epithelium formed a perle" in the lacuna.—Dr Grant remarked that the condition was apt to disappear without apparent cause.—After some observations by Mr W J Chichele Nourse, Dr W Jobson Horne, and the President Mr Lennox Browne and Dr Wingrave replied.—Dr W H Kelson showed a case of Tuberculous Tracheitis. The patient, whose two brothers died from phthisis, had congestion of the larynx and ulceration at the upper and anterior part of the trachea. The sputa contained quantities of tubercle bacilli.—Dr Kelson also read notes of a case of Singer's Nodes on both Cords in a choir boy —Dr Grant showed a case of Congenital Papillomata of the Larynx in a female aged 23 years, who had worn a tracheotomy tube from infancy until the time that she consulted him four weeks ago Her voice then resembled that of functional aphonia. The lips and tongue moved but there was no phonation Dr Grant removed the papillomata with forceps and snare and cleared the larynx, so that the patient was able to breathe through the natural channel Later he closed the tracheal wound. The patient had now a fair voice.—Mr Lennox Browne congratulated Dr Grant upon the result. The patient, who was before voiceless, could now utter a good vowel sound. He could recall only one similar case. In that instance it was some time after the removal of the papillomata before the patient was able to speak —Dr Kelson pointed out that the case was evidence in support of the view that tracheotomy alone was not curative in cases of papillomata of the larynx.—After a few remarks by the President Dr Grant replied.—Dr Grant also showed a Bent Glass Tube of a useful form devised by Dr Leduc of Nantes for enabling a patient to apply remedies in the form of powder to his own larynx —The President showed 1. Photographs of the new electrical department at the Glasgow Royal Infirmary Besides apparatus for x rays and high frequency currents and a very large static machine there was a huge and very powerful electro-magnet for removing foreign bodies from the trachea, &c. 2. Photographs of a case of Cancer of the Nose in a woman, aged 60 years Two months ago an old wart took on a very rapid growth. On removal of the external mass it was found to have penetrated the cartilage and to be invading the tissues inside the nose. The case was now under treatment by the x rays

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND —The summer meeting of this society was held at St. Bartholomew's Hospital Medical School on July 3rd and 4th Mr C B. Lockwood the President being in the chair The meeting which was well attended both by the London and provincial members commenced each day at 3 P M Amongst the visitors present was Professor Fürst of Lund Sweden. The following communications were brought before the notice of the society —Dissections of Two Twin Monsters with lantern illustrations and specimens by Dr R. J A. Berry (Edinburgh), Flexor Carpi Radialis of an Elephant showing Great Development of Elastic Tissue, by Mr R. H. Burne a specimen showing a Band formed by a Persistent Vitelline Artery by Mr R. C. Bailey Two Hearts showing peculiarities of the Great Veins by Dr D N Nabarro the Relations of the Deeper Parts of the Brain to the Surface, illustrated by specimens, photographs and lantern slides by Professor J Symington (Belfast) a lantern demonstration on the Extent to which Lumbar Segments of the Body have been transmuted to Sacral *in the Evolution of Man and the Higher Primates*, by Dr Arthur Keith Vestigial First Rib by Professor Macphail (Glasgow) a Minimal Form of Fissura Facialis, by Mr N B Harman Some Points on the Topographical Anatomy of the Thoracic and Abdominal Viscera in Hylobates Hainanu, by Professor C. J Patten (Sheffield), exhibition of the Skull and other Bones from a case of Acromegaly by Professor A. F Dixon (Cardiff), a preliminary communication on the Development of the Pericardium by Professor Arthur Robinson the Sternal Angle in Man, by Dr Walter Kidd, the Form of the Human Spleen, by Mr R. K. Shepherd (Cardiff). On the morning of July 3rd the members and visitors made a formal visit to the museum of the Royal College of Surgeons of England to view the new museum specimens Mr R. H Burne kindly received them and showed the recent additions which had been made to the museum. In the evening the annual dinner was held at the Café Royal, Regent-street, and was attended by upwards of 40 members and guests. Amongst the latter were Sir W S. Church, Mr A. Willett, Mr H. T Butlin Professor Haddon, Mr F G Hallett, Dr J Calvert, and Professor Fürst. The dinner was one of the most successful that has been held by the society Through the kindness of the officers of the Zoological Society of London arrangements were made for a visit to the Zoological Gardens, Regent's Park on the morning of July 4th, when the members of the society had the special advantage of being accompanied by Mr Frank Beddard F R.S After a tour of the gardens had been made the provincial members and guests were entertained at luncheon by the London members of the society In the evening the President entertained the provincial members at dinner

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND —A meeting of this society was held on July 16th Dr J H. Stowers the President, being in the chair —Dr A Eddowes showed (1) a case of Dysidrosis in the form of Erythema Exudativum (a private patient) and (2) a case of Bullous Eruption.—Dr T D Savill showed a case of Hebra's Prurigo.—Dr E. G Graham Little showed (1) a Case for Diagnosis (2) a case of Acne Scrofulosorum, and (3) a case of Lichen Hypertrophicus with extensive lesions of the mucous membrane of the mouth —The President showed cases of (1) Lupus (2) Lupus Erythematosus and (3) Alopecia.—Dr E. Stainer showed (1) a Girl aged 12 years with Linear Papilloma of the Arm and (2) Tuberculide Eruption on the legs of a boy aged nine years.—At the annual meeting the following officers were elected —President, Dr Stowers. President-elect Dr H. Waldo. Vice-Presidents Dr P S. Abraham, Dr R. L. Bowles, Sir Alfred Cooper Dr H. Radcliffe Crocker Sir G F Duffey Dr James Galloway Dr A. J Harrison, J P Dr Robert Liveing and Dr H. H. Phillips-Conn. Treasurer Dr W T Freeman. Council Dr W Beatty Dr H. A. G Brooke, Dr A. Eddowes Dr A. J Hall Mr T J Hitchins, Dr Graham Little, Mr George Pernet, Dr Leslie Roberts, Mr G W Sequeira, Dr R. Travers Smith Dr Stainer and Dr C H. Thompson. Secretaries Mr Arthur Shillitoe and Dr Wilfrid B Warde.

Ophthalmic Myology A Systematic Treatise on the Ocular Muscles By G C SAVAGE, M D Professor of Ophthalmology in the Medical Department of Vanderbilt University Nashville Tennessee Published by the Author 1902. Crown 8vo. Pp 589

THE study of the actions of the extrinsic muscles of the eye has been pursued of late years with remarkable energy and enthusiasm by the Americans and the writings of Stevens Duane Swan Burnett, H. Wilson, Culbertson Reber and many others have done much to elucidate our knowledge of these muscles and to explain the consequences of their excessive and of their defective power the appreciation of which has an important bearing on treatment. About the middle of the last century it was customary to perform a tenotomy upon almost every case of squint that appeared amongst the out patients of a hospital and though doubtless many cases proved fairly successful there were others in which the results were disastrous the patient leaving the hospital with a disfigurement greater than that from which he had expected to be relieved. In course of time the study of the refraction of the eyes of the form of the globe of the pathological conditions in the interior of the eye as well as of the extrinsic neuro-muscular apparatus, aided by considerable improvements in the methods of operation, has materially assisted the surgeon in selecting appropriate cases sinus The dura mater bulged into the opening and no pulsation was visible, but pulsation could be felt by pressing in with the finger The dura mater was then opened and there was very marked protrusion of the cerebellum, demonstrating the high degree of intracranial tension A pair of fine sinus forceps was introduced in an inward and forward direction for about two inches and again in both an upward and downward direction, each time with a negative result The wound was rapidly stitched up and a similar opening was made on the left side A similar bulging of dura mater and cerebellum was found The sinus forceps was pushed in an inward and forward direction and at a depth of about half an inch from the surface an abscess was opened and thick very foul-smelling pus was evacuated. The forceps on being pushed further gave a sensation to the touch as if it was in a fair sized cavity The forceps was opened in withdrawal to enlarge the opening The moment the pus oozed out it was noticed that spontaneous respiration began and continued from this time onwards, though artificial respiration had previously been necessary for 80 minutes A rubber drainage tube was inserted and altogether about two or three drachms of stinking pus were evacuated A hole was made in the base of the flap, the tube being brought through this and stitched to the skin The flap was stitched up, the wound was dressed, and the patient was sent back to the ward The breathing remained somewhat of the Cheyne Stokes character The patient became conscious about three hours after, but then had three convulsive attacks, and he died six hours after the termination of the operation

Necropsy —At the post-mortem examination it was found that the only abnormal condition in the cranial cavity was a ragged-walled abscess cavity occupying the major portion of the left lateral lobe of the cerebellum There was no meningitis and no caries or necrosis was perceptible on the intracranial aspect of the temporal bones There was general enlargement of the mesenteric glands and a patch of lymph was found on the pericardium No other abnormal condition was observed

Remarks by Mr CUNNING —The reason for calling attention to this case is that the diagnosis of cerebellar abscess is still a matter of difficulty and the localisation is of still greater difficulty For this reason I think that all cases should be recorded, as each may contribute something to our store of knowledge and help in the treatment of this dangerous condition. There is a feature in this case, also, that, so far as I know, has not been noted before—that the whole operation was performed during the maintenance of artificial respiration and the necessity for the performance of the latter was abolished as soon as the abscess was opened. The interesting points of the case are as follows

1. The difficulty of diagnosis For 10 days the patient was under observation and his only constant symptom was abnormal slowness of the pulse The headache, mental slowness, deafness, vomiting, and tenderness over the mastoid all improved. Then vomiting subnormal temperature, giddiness, and increased mental dulness came on

2. The localisation of the abscess The points given by Acland and Ballance quoted in Jacobson's "Operations of Surgery" are (1) paralysis of the upper extremity on the same side, (2) conjugate deviation of the eyes to the opposite side, (3) lateral nystagmus, (4) exaggerated knee jerk on the side of the lesion, (5) a tendency to face towards the side of the lesion in walking, (6) staggering gait and a tendency to fall towards the side opposite to the lesion, and (7) attitude in bed, the patient lying on the side opposite to the lesion Of these different symptoms, there were absent in the present case paralysis of the arm, conjugate deviation of the eyes, and lateral nystagmus The patient was never examined as to his gait. So the only localising symptoms were (1) exaggerated knee jerk on the left side, and (2) inability to lie on the right side The former turned out to be accurate but the latter did not.

3 The anæsthetic. The fact of the pulse rate increasing from 42 to 120 I can only explain as due to pressure on the vagus centre rendering it more easily inhibitable by chloroform than when it is in a normal condition Whether a different result might have been brought about if no anæsthetic had been given is to be considered. Where there is so much pressure upon the medulla it may be that the depressing influence of the anæsthetic is sufficient to upset the already precariously kept balance On the other hand, it would not be easy to explore both sides of the cerebellum th local anæsthesia, though it might be worth trying It has been asserted recently that chloroform always produces heart-failure before respiratory failure In this case there seems little doubt that chloroform precipitated the respiratory failure without interfering greatly with the action of the heart.

4 The respiration The beginning and carrying through of the whole operation, in spite of the patient making no attempt at breathing, was amply compensated for by the immediate return of activity in the respiratory centre when the abscess was opened One other point as to the cause of death is whether the cavity being emptied quickly caused œdema to occur in the medulla oblongata when the pressure was suddenly relieved—whether it would have been better to allow the cavity to empty very slowly so that vessels with their walls paralysed by pressure might have time to recover

I have to thank Mr Roughton for his great courtesy in allowing me to make use of this case

---

NORTHAMPTON GENERAL INFIRMARY

A CASE OF THROMBOSIS OF THE CEREBRAL SINUSES FOLLOWING ON CHLOROSIS, RECOVERY

(Under the care of Dr P S HICHENS)

THROMBOSIS of the cerebral sinuses occurs in two forms which differ greatly from one another In one form the coagulation of the blood is produced by septic organisms generally spreading from the middle ear In this septic variety of thrombosis surgical interference is indicated, for spontaneous recovery is extremely rare. In the other form the thrombosis is due to the increased coagulability of the blood which results from anæmia, and the following case is a good example of it There can be but little doubt about the diagnosis, for there is no other known condition capable of producing all the signs and symptoms present. For the notes of the case we are indebted to Dr George H Lewis, house physician.

A domestic servant, aged 18 years, was admitted into the Northampton General Infirmary on Jan 10th, 1902, complaining of shortness of breath, palpitation, amenorrhœa, and the other symptoms common to chlorosis In addition to these she complained of vomiting which for the past two or three weeks had been getting more frequent, she said that on the day prior to admission she had vomited a little blood With the exception of an attack of chlorosis two years ago her general health had been good On admission she walked into the hospital and did not appear to be seriously ill She was somewhat pale but presented no symptoms differing from a case of ordinary chlorosis which is so frequently met with in the out-patient department of any hospital. On examining her chest a loud systolic murmur was heard in the pulmonary area and there was a well-marked bruit in the veins of the neck There was nothing abnormal in the lungs The urine was acid, of specific gravity 1018, and contained no abnormal constituents The history of hæmatemesis was so indefinite that peptonised milk was given in small quantities at frequent intervals and produced no ill effects Two days after admission (Jan 12th) the patient complained of severe frontal headache and pain in the left lumbar region Her temperature rose to 102° F and the headache became more and more severe. Her face was dull and expressionless, she was slow in answering questions, and she gazed about her with a vacant stare At one time she was very restless, trying to get out of bed, whilst at another she lay very quiet and helpless Occasionally she cried out. She vomited twice and gradually passed into a state of unconsciousness, not recognising her relatives and passing her fæces and urine in bed Her pupils were widely dilated and a specimen of her urine withdrawn by a catheter contained a large amount of albumin. There were no spots on the abdomen suggestive of enteric fever and no enlargement of the spleen was observed She remained in this condition for about 36 hours when she again began to grow restless, then to recognise her relatives and to show other signs of gradually returning consciousness, and on the 17th (five days after the onset of the headache, &c.) she was able to answer simple questions She said that she was free from pain in her forehead. She drank her milk readily but still passed fæces and urine in bed On examining her eyes there was found to be distinct optic neuritis in each eye and a small hæmorrhage was seen below the left optic disc. By the 25th the cerebral symptoms had entirely disappeared and the albumin had greatly diminished in the urine there being only a faint trace, but the optic neuritis had slightly increased especially in the right eye On the following day she complained of great pain in the right thigh and leg which was accompanied by a large amount of swelling presenting a typical example of a thrombosis of the right femoral vein. The temperature, which had been normal for 10 days, rose to 101 6° The pain and swelling in the leg lasted for a few days and then gradually subsided, and on Feb 11th all the symptoms of the thrombosis in the femoral vein had disappeared there was no albumin in the urine and the optic neuritis had slightly diminished. A fortnight later the optic neuritis had entirely disappeared from the left eye, but there was still some absence of definition of the margin of the right disc, but no distinct exudation and no hæmorrhage into the retina were present. The vision equalled $\frac{6}{6}$ in each eye. The patient made an uninterrupted recovery the percentage of hæmoglobin rising from 30 to 68 per cent , the red blood corpuscles amounted to 4 000,000 per cubic millimetre at the time of admission and did not increase or diminish She was discharged from the hospital on March 15th. She has since attended as an out-patient three or four times and has shown no untoward symptoms, she is no longer short of breath and has no sickness and menstruation has recommenced.

Remarks by Dr LEWIS.—After reading Dr C O Hawthorne's interesting article in the *British Medical Journal* of Feb. 8th 1902, in which he says It is certain that double optic neuritis may be included among the symptoms of thrombosis of the cerebral sinuses, I thought that the above case might be worth recording The chief points of interest are, I think its extreme rarity when compared with the large number of cases of anæmia in girls the presence of almost all the symptoms associated with sinus thrombosis—viz. headache, mental dulness, unconsciousness vomiting dilatation of the pupils and double optic neuritis and the occurrence of thrombosis in the right femoral vein. Another interesting point, but one which I am not prepared to account for was the presence of pain in the left lumbar region associated with a large amount of albumin in the urine which occurred simultaneously with the frontal headache. Professor T Clifford Allbutt in his ' System of Medicine," vol. vi. p 201 states that of 78 cases of venous thrombosis associated with chlorosis in only six of them was there thrombosis of the cerebral sinuses and of the lower extremities in 32 of the cases there was no thrombosis of the extremities, only thrombosis of the cerebral sinuses. These figures are apt to make one imagine that thrombosis more commonly occurs in the sinuses than in the extremities but Professor Allbutt's explanation that 'thrombosis of the extremities is far more frequently met with, but in a large number of cases the effects produced are not so serious as to make the case sufficiently interesting for publication will be agreed to by all.

The thrombosis in the femoral vein had many interesting features in its development when compared with that of the cerebral sinuses the onset of pain and the similar rises in the temperature indicated that similar changes were occurring somewhere in the system, the mental dulness, headache, optic neuritis, &c. localising the one in the cerebral sinuses, and the swelling of the thigh and the leg localising the other in the femoral vein. The diagnosis of sinus thrombosis is one to which some may take exception but I do not know of any other condition occurring in chlorosis which would account for the above symptoms , the thrombosis in the femoral vein occurring at a later date seems to me to justify the diagnosis being made.

I am indebted to Dr Hichens for his kind permission to publish this case

EDINBURGH OBSTETRICAL SOCIETY

Hæmorrhage during Pregnancy

A SPECIAL combined meeting of this society with the Glasgow Obstetrical and Gynæcological Society was held in Edinburgh on July 9th Dr JAMES RITCHIE, the President of the former being in the chair

Dr ROBERT JARDINE (Glasgow) opened a discussion on Hæmorrhage during the Later Months of Pregnancy and Early Stages of Labour Unavoidable hæmorrhage arose from the separation of an abnormally situated placenta—that was one entirely or partly attached below the retraction ring As soon as dilatation began separation must occur and this separation meant the opening up of sinuses and consequent hæmorrhage. In the central variety the entire placenta must separate and very severe hæmorrhage result , in the lateral variety the greater part of the placenta must separate and severe hæmorrhage also occur while in the marginal variety when only a small portion was below Bandl's ring the bleeding would not be great. This last was probably more frequent than was supposed and was the cause of slight hæmorrhage in the early stages of labour In the treatment of unavoidable hæmorrhage, the viability of the fœtus must be considered. If not viable then palliative measures should be tried, unless the hæmorrhage was very severe Absolute rest in bed with perhaps an opiate and attention to the bowels and diet were all that might be required. Styptics were of no use. The patient and friends must be warned to notify any recurrence of bleeding immediately Unfortunately many women were so accustomed to large losses of blood that they were not easily alarmed and they might delay until it was too late. If the fœtus was viable and the hæmorrhage was severe, then active treatment must be carried out. The most efficient way to stop the bleeding was plugging If the os was not dilated or only slightly then plugging should be resorted to if possible inserting one plug into the os and afterwards the vagina should be packed till it was completely filled If the os was dilated sufficiently then a Barnes or a Champetier de Ribes bag might be used but if the os was dilated sufficiently to permit of the insertion of one of these then it would permit of the performance of bipolar version in a head or transverse case so as to bring a leg down into the vagina. In a breech case one leg should be brought down as soon as possible The plug should be removed in a few hours and the os was usually found dilated to permit of further treatment. Once a leg was down then gentle traction would control the hæmorrhage. The labour should not be hastened after this as forcible traction of the child through an os not completely dilated would produce laceration of the cervix and very serious hæmorrhage owing to its special vascularity in this condition. If the os was quite dilated then delivery should be effected as quickly as possible by version or by forceps. If the placenta was central the hand must be passed through or round it. Stripping off the placenta was useful, as it allowed dilatation of the os to occur more easily In the marginal placenta prævia the membranes might be punctured and the uterus stimulated by friction till the placenta was pressed on by the presenting part. After the birth of the child if the placenta did not come away at once it should be removed If post-partum hæmorrhage occurred ergotin should be given hypodermically and pressure applied bimanually Hot water douching was of questionable advantage as it might wash away the clots out of the sinuses and so promote hæmorrhage Dr Jardine had of late been using 30 grains of suprarenal gland to the pint for douching and it seemed to have a good effect But if there was any tendency to post partum hæmorrhage he invariably plugged the uterine cavity the cervix and the vagina. Reference was then made to the operation of Cæsarean section in placenta prævia as first proposed by Lawson Tait. Eight cases had thus been treated by Cæsarean section or Porro's operation , five mothers and six children were saved Two cases were hopeless before operation But even omitting these two the resulting mortality was much higher than was present in cases treated by the other method where there was a mortality of about 1 in 20. The treatment by abdominal section seemed unjustifiable. Accidental hæmorrhage might be external or internal. In the external if the uterine contractions were active then the membranes should be ruptured and the uterus massaged or a tight binder applied. If the bleeding continued then the uterus should be emptied as soon as possible by turning or by forceps Dr Jardine referred to the Rotunda method of plugging and the reasons adduced for its use, but he could not agree with their theory In these cases the uterine wall was not in a normal condition. If strong contractions were occurring then plugging might be used, but if there were no contractions then there would be great risk of converting an external into an internal hæmorrhage He had seen one case in which this happened with fatal result. If the hæmorrhage was severe the uterus should be emptied as quickly as possible, the os being dilated by hand or by a Champetier de Ribes bag As soon as the child was born the hand should be inserted into the uterus and the placenta and clots should be removed Ergotin should be given and the uterus plugged if post partum hæmorrhage was occurring The plug could be wrung out of suprarenal extract solution. A saline infusion should be given if much blood had been lost or if there had been much shock Concealed internal hæmorrhage was the most fatal of all the forms Rupturing the membranes would only make more room for blood to be poured out, and delivery by accouchement forcé was not very hopeful if the hæmorrhage was severe In Dr Jardine's experience of many cases such treatment was disastrous He favoured removal of the uterus by Porro's operation. A helpful symptom in diagnosing this condition was that the patient complained of severe pain of a continuous character in the abdomen If the condition was recognised early then the membranes should be ruptured before there was sufficient bleeding to cause collapse. Another source of hæmorrhage in the early stage of labour might be a commencing spontaneous rupture of the uterus, but it could not be diagnosed till the rupture had occurred, when abdominal section and removal of the uterus should be carried out.

After Dr **ROBERT BARNES** (London) had made some remarks on the use of bags as dilators,

Professor **A. R. SIMPSON** referred to the pleasure that the societies had in hearing the Nestor of British midwifery open the discussion He referred to the carelessness of women suffering from hæmorrhage. Many of the subjects of placenta prævia suffered previously from endometritis and thus were accustomed to considerable losses of blood, so that the hæmorrhage during pregnancy did not alarm them. He believed in palliative treatment at first, warning the patient to give immediate intimation of any recurrence, if this should occur the active interference should be at once carried out The worst and most fatal cases were those where there had been repeated hæmorrhages and where only a little was sufficient at last to cause death

Dr **J M MUNRO KERR** (Glasgow) referred to his experience in 10 cases He considered it important to diagnose the variety and apply the treatment accordingly

Dr **D BERRY HART** considered that the best treatment if the hæmorrhage was severe was to dilate the os rapidly till it would admit two or three fingers, then to perform bipolar version, bring down a foot, and allow the case aftewards to be terminated naturally By doing this they would save more children than if they hastened the termination of the labour

Professor **J A. C KYNOCH** (Dundee) considered that the treatment mainly resolved itself into that by bipolar version. The os must be dilated to permit of this being carried out and this could be accomplished by packing or by the use of bags, but he had never required to use these, having always attained this object by digital dilatation Careful attention should be given to asepsis in all the procedure, as these cases had a special tendency to sepsis He considered rapid delivery to be disastrous

Dr **J HAIG FERGUSON** did not consider Porro's operation or Cæsarean section necessary in any case of accidental hæmorrhage If labour had commenced in such a case he ruptured the membranes and left to nature, applying forceps or turning if afterwards required

Dr **J C HERBERTSON** (Glasgow) considered that the treatment had to be modified according to the position of the patient, as if she were of the working class she could not lie in bed for a long period and she would increase the danger by getting up Such a case would require interference, whereas another in better circumstances would only necessitate watching

Dr **F W N HAULTAIN** remarked that the discussion had revealed a lamentable state of obstetric nomenclature, as was evidenced by the use of the terms "overlapping," "partial," "lateral," &c, for the same condition of placenta. If the hæmorrhage was not urgent he gave the patient the benefit of the doubt and used palliative measures, but he warned the patient of the risk. He considered that the patient should be informed of the condition and be allowed to decide for herself whether she cared to run the risk Those of the patients who died did so from post-partum hæmorrhage and this often consisted in a steady ooze of blood which pressure and the hot douche would not stop Plugging was the only method to stop it, and yet there were text-books which taught students not to do so in post-partum hæmorrhage. He supported the treatment of concealed accidental hæmorrhage by abdominal operation.

Dr **ALEXANDER MILLER** (Glasgow) had no faith in palliative measures, if the hæmorrhage were severe and the patient near full time he administered chloroform, used digital dilatation, performed podalic version, and delivered the child as soon as possible The sooner the uterus was emptied the better

Dr **MICHAEL DEWAR** stated that he had only met three cases of placenta prævia in 2000 cases attended in practice. The great point with a practitioner was to distinguish between accidental and unavoidable, and this was not always easy, especially if the os was not dilated and the blood was escaping in considerable gushes

Dr **S MACVIE** (Chirnside) said that country practitioners considered these cases from a different point of view, there was no cut-and dry system for them He did not put the decision of the treatment to the mother but kept her in the dark so as not to put her into an alarming state of nervous excitement. He first palpated the uterus carefully to locate the placenta if possible, as this helped subsequent treatment very much He dilated the os by the fingers and turned till he got hold of a foot, this when pulled down might stop external bleeding but yet some internal hæmorrhage might be occurring and he felt more satisfied when the body was down. He alluded to the tight packing that had been recommended during the discussion and advised caution, as a neighbour of his had plugged the vagina so tightly in one case as to cause sloughing

The **PRESIDENT** referred to the general opinion in favour of plugging in post-partum hæmorrhage Statistics of the frequency of placenta prævia differed very much and this affected the mortality percentage. He believed that many cases of marginal placenta prævia were overlooked in private practice The diagnosis of placenta prævia from the examination of the after birth by measuring the distance between the rupture in the membranes and the edge of the placenta was not trustworthy

Dr **JARDINE**, in reply, referred to several cases of placenta prævia which had a previous history of endometritis or curetting and there was probably a causal relation He always carried out antiseptic treatment very carefully He thought that a mortality of 23 per cent. was too high, of 150 cases in the Glasgow Maternity he found that the death rate was 5 per cent. in more recent years and 17 per cent. previously, so that the advance in treatment had influenced the mortality These cases were often admitted moribund into hospital and swelled the mortality He adhered to his opinion in advising Porro's operation in cases of serious concealed hæmorrhage. There might be placenta prævia cases converted into concealed by internal hæmorrhage, but whatever the cause if the uterus was so dilated that the walls seemed ready to burst he considered operation to be the woman's best chance. He had not yet operated in such a case but he intended doing so in the next one as in all such cases which he had met the patients had died under other treatment.

Dr **A. W RUSSELL** and Dr **G BALFOUR MARSHALL** (Glasgow) also joined in the discussion

The Fellows afterwards dined together

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION—A meeting of this society was held on July 11th, Dr J Macintyre, the President, being in the chair—Dr V H Wyatt Wingrave read notes of a case of Bilateral Adductor Paralysis in a boy, aged 7 years—Mr Lennox Browne inquired if adenoids were present or if there was any symptom pointing to reflex disturbance—Dr J Dundas Grant said that he had seen the patient and had found the larynx to be normal in every respect. He regarded the case as one of hysterical aphonia.—Mr E. Dennis Vinrace asked if there had been a tendency to relapse.—Dr. Wingrave, replying said that he had removed adenoids. One application of the interrupted current quickly restored the voice.—Mr Lennox Browne read notes of a case of Keratosis of the Tonsils without Leptothrix in a young adult. He had removed the tonsils, of which Dr Wingrave now showed microscopical sections.—Dr Wingrave described two varieties of Tonsillar Keratosis one in which the horny growth projected through the open mouth of the crypt, the other where, the orifice being closed, the horny epithelium formed a perle" in the lacuna.—Dr Grant remarked that the condition was apt to disappear without apparent cause.—After some observations by Mr W J Chichele Nourse Dr W Jobson Horne, and the President, Mr Lennox Browne and Dr Wingrave replied.—Dr W H Kelson showed a case of Tuberculous Tracheitis. The patient, whose two brothers died from phthisis, had congestion of the larynx and ulceration at the upper and anterior part of the trachea. The sputa contained quantities of tubercle bacilli.—Dr Kelson also read notes of a case of Singer s Nodes on both Cords in a choir boy —Dr Grant showed a case of Congenital Papillomata of the Larynx in a female, aged 23 years, who had worn a tracheotomy tube from infancy until the time that she consulted him four weeks ago Her voice then resembled that of functional aphonia. The lips and tongue moved but there was no phonation Dr Grant removed the papillomata with forceps and snare and cleared the larynx so that the patient was able to breathe through the natural channel Later he closed the tracheal wound. The patient had now a fair voice.—Mr Lennox Browne congratulated Dr Grant upon the result. The patient, who was before voiceless could now utter a good vowel sound He could recall only one similar case In that instance it was some time after the removal of the papillomata before the patient was able to speak —Dr Kelson pointed out that the case was evidence in support of the view that tracheotomy alone was not curative in cases of papillomata of the larynx —After a few remarks by the President Dr Grant replied.—Dr Grant also showed a Bent Glass Tube of a useful form devised by Dr Leduc of Nantes for enabling a patient to apply remedies in the form of powder to his own larynx.—The President showed 1. Photographs of the new electrical department at the Glasgow Royal Infirmary Besides apparatus for x rays and high frequency currents and a very large static machine there was a huge and very powerful electro-magnet for removing foreign bodies from the trachea, &c. 2. Photographs of a case of Cancer of the Nose in a woman, aged 60 years Two months ago an old wart took on a very rapid growth. On removal of the external mass it was found to have penetrated the cartilage and to be invading the tissues inside the nose. The case was now under treatment by the x rays

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND —The summer meeting of this society was held at St. Bartholomew's Hospital Medical School on July 3rd and 4th, Mr C B Lockwood the President being in the chair The meeting which was well attended both by the London and provincial members commenced each day at 3 P M Amongst the visitors present was Professor Fürst of Lund Sweden. The following communications were brought before the notice of the society —Dissections of Two Twin Monsters, with lantern illustrations and specimens, by Dr R. J A. Berry (Edinburgh) Flexor Carpi Radialis of an Elephant showing Great Development of Elastic Tissue, by Mr R. H. Burne a specimen showing a Band formed by a Persistent Vitelline Artery by Mr R C Bailey Two Hearts showing peculiarities of the Great Veins, by Dr D N Nabarro the Relations of the Deeper Parts of the Brain to the Surface illustrated by specimens, photographs and lantern slides by Professor J Symington (Belfast) a lantern demonstration on the Extent to which Lumbar Segments of the Body have been transmuted to Sacral in the Evolution of *Man and the Higher Primates*, by Dr Arthur Keith Vestigial First Rib by Professor Macphail (Glasgow) a Minimal Form of Fissura Facialis, by Mr N B Harman Some Points on the Topographical Anatomy of the Thoracic and Abdominal Viscera in Hylobates Hainanus by Professor C. J Patten (Sheffield), exhibition of the Skull and other Bones from a case of Acromegaly by Professor A. F Dixon (Cardiff), a preliminary communication on the Development of the Pericardium by Professor Arthur Robinson the Sternal Angle in Man, by Dr Walter Kidd the Form of the Human Spleen by Mr R. K. Shepherd (Cardiff). On the morning of July 3rd the members and visitors made a formal visit to the museum of the Royal College of Surgeons of England to view the new museum specimens Mr R. H. Burne kindly received them and showed the recent additions which had been made to the museum. In the evening the annual dinner was held at the Café Royal Regent-street, and was attended by upwards of 40 members and guests. Amongst the latter were Sir W S. Church Mr A. Willett, Mr H. T Butlin Professor Haddon Mr F G Hallett, Dr J Calvert, and Professor Fürst. The dinner was one of the most successful that has been held by the society Through the kindness of the officers of the Zoological Society of London arrangements were made for a visit to the Zoological Gardens, Regent s Park on the morning of July 4th, when the members of the society had the special advantage of being accompanied by Mr Frank Beddard F R.S After a tour of the gardens had been made the provincial members and guests were entertained at luncheon by the London members of the society In the evening the President entertained the provincial members at dinner

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND —A meeting of this society was held on July 16th Dr J H. Stowers, the President, being in the chair —Dr A Eddowes showed (1) a case of Dysidrosis in the form of Erythema Exudativum (a private patient) and (2) a case of Bullous Eruption.—Dr T D Savill showed a case of Hebra s Prurigo.—Dr E. G Graham Little showed (1) a Case for Diagnosis (2) a case of Acne Scrofulosorum, and (3) a case of Lichen Hypertrophicus with extensive lesions of the mucous membrane of the mouth —The President showed cases of (1) Lupus (2) Lupus Erythematosus and (3) Alopecia.—Dr E. Stainer showed (1) a Girl aged 12 years with Linear Papilloma of the Arm and (2) Tuberculide Eruption on the legs of a boy aged nine years.—At the annual meeting the following officers were elected —President, Dr Stowers. President-elect Dr H. Waldo. Vice-Presidents Dr P S. Abraham Dr R. L. Bowles, Sir Alfred Cooper Dr H Radcliffe Crocker Sir G F Duffey, Dr James Galloway Dr A. J Harrison, J P Dr Robert Liveing and Dr H. H. Phillips-Conn. Treasurer Dr W T Freeman. Council Dr W Beatty Dr H A. G Brooke Dr A. Eddowes, Dr A. J Hall Mr T J Hitchins, Dr Graham Little Mr George Pernet, Dr Leslie Roberts Mr G W Sequeira, Dr R. Travers Smith Dr Stainer and Dr C H. Thompson Secretaries Mr Arthur Shillitoe and Dr Wilfrid B Warde.

Reviews and Notices of Books.

Ophthalmic Myology A Systematic Treatise on the Ocular Muscles. By G C. SAVAGE, M D Professor of Ophthalmology in the Medical Department of Vanderbilt University Nashville, Tennessee Published by the Author 1902. Crown 8vo. Pp 689

THE study of the actions of the extrinsic muscles of the eye has been pursued of late years with remarkable energy and enthusiasm by the Americans and the writings of Stevens Duane Swan Burnett, H. Wilson Culbertson Reber and many others have done much to elucidate our knowledge of these muscles and to explain the consequences of their excessive and of their defective power the appreciation of which has an important bearing on treatment. About the middle of the last century it was customary to perform a tenotomy upon almost every case of squint that appeared amongst the out-patients of a hospital and though doubtless many cases proved fairly successful there were others in which the results were disastrous the patient leaving the hospital with a disfigurement greater than that from which he had expected to be relieved. In course of time the study of the refraction of the eyes of the form of the globe of the pathological conditions in the interior of the eye, as well as of the extrinsic neuro-muscular apparatus aided by considerable improvements in the methods of operation, has materially assisted the surgeon in selecting appropriate cases for operation and has enabled him to feel some confidence in the good effects which he can promise to the patient.

A precise knowledge of the action of the muscles is fundamental and Dr Savage deals with these actions at great length and with considerable originality The reader must not expect to find any anatomical or histological details in regard to the muscles of the eye. There is only a broad description of their attachment, the author dealing entirely and exclusively with their action To abbreviate circumlocution a new nomenclature has of late years been introduced and is now constantly employed, embracing such terms as "esophoria," "exophoria," "hyperphoria," "cataphoria," "cyclotropia," and "cyclophoria," terms to which no exception can be taken since they are legitimately formed and precise The earlier pages of the volume are occupied with the planes and axes of the eye, the explanation of single vision with two images, and the nature of the horopter, which, he thinks, would be more correctly designated the "monoscopter," since it signifies the circle of binocular single vision.

The mode in which Dr Savage deals with the defects of the ocular muscles may be illustrated by a reference to his chapter on Exophoria. This condition, which is not quite equivalent to that formerly termed "external squint," is here defined to be "a *tendency* on the part of the external recti muscles and their synergists to make the visual axis deviate from the point of fixation" Now exophoria may be of two kinds, intrinsic exophoria or pseudo exophoria, or the two conditions may be associated In intrinsic exophoria the external recti overpower the internal recti either owing to their superiority in size or their more advantageous insertion or to the greater functional activity of their nerve centres, and to determine the treatment that is required it is necessary to distinguish between sthenic and asthenic exophoria. "Exophoria with abduction of less than 8° and abversion of less than 50° is asthenic and clearly indicates that the externi should not have their tension lessened and just as clearly indicates that the interni must have their tension increased Exophoria with abduction taken with the prism or phorometer of more than 8° and abversion taken with the perimeter of more than 50° is sthenic and the case should be treated with the view of lessening the tension of the externi" In view of the disastrous results of operation in some imperfectly understood cases rules like this, though they may require modification in particular instances, are of considerable value and a great advance on the haphazard mode that was formerly in use.

Dr Savage has arrived at the conclusion that "all tests for lateral heterophoria are wholly unreliable within the first few hours after eyes have been brought under the influence of a mydriatic" and he makes out a good cas [illegible] port of his view The mydriatic, he says, acts [illegible] here extremities of the accommodative nerve fi [illegible] the accommodative centre which remains susc [illegible] ion by the demands upon it from the guiding se [illegible] he enforced rest of the muscles of accommo [illegible] images become progressively less distinc [illegible] sensation calls on the accommodative [illegible] images, and the impulse [illegible] but [illegible] irresponsive Stronger [illegible] effect, but for every deg [illegible] carried into effect by the [illegible] corresponding *tendency* to [illegible] verging centre, and this [illegible] abnormal action, the inter [illegible] sensation is robbed of its [illegible] heterophoria an increased pse [illegible]

In his account of the o [illegible] enumerating the usual instrum [illegible] has just been devised by Dr [illegible] and named the "tendonometer," which consists of a hook that can be passed under the tendon and a graduated shaft suspended by a coil spring in a hollow metal handle It is claimed that by means of this little instrument the resistance of each of the ocular muscles or of uncut fibres when a partial tenotomy is being done can be estimated.

Dr Savage's work as a whole presents many features that are novel, especially those dealing with the obliquity of the images in cases of oblique astigmatism which are well worthy of perusal, and the lines of treatment he suggests are always sensible, but it is hardly a book from which a student will derive much advantage It is adapted for the teacher and will accomplish its end if it leads him to think over the difficult problems connected with troubles of the ocular muscles

---

The Earth in Relation to the Preservation and Destruction of Contagion. Being the Milroy Lectures delivered at the Royal College of Physicians in 1899, together with other papers on Sanitation By GEORGE VIVIAN POORE, M D, F R C P Lond, Professor of the Principles and Practice of Medicine, University College, London, Physician to University College Hospital. London Longmans, Green, and Co 1902. Pp 257 Price 5s net

DR. POORE in his brief preface says that he feels no excuse is needed for the republication of the lectures and papers included in this volume, for they deal with subjects of national importance The book, as stated on the title page, contains the Milroy Lectures of 1899, an address on Enteric Fever which was delivered before the Royal Medical and Chirurgical Society, and four papers on other subjects Although the substance of these lectures and addresses may be familiar to readers of THE LANCET, many of them will welcome their republication, and we particularly recommend the book to medical officers of health in rural districts and to country practitioners Dr Poore has for a long series of years conducted experiments in regard to the treatment of house refuse (using the term in its widest sense) and all he says on the subject is of great interest Year by year the problems connected with drainage and water supply are giving more trouble throughout the country and nothing can be more extravagant in cost and more prejudicial to health than many of the ill-devised and badly executed drainage schemes which are being carried out in all parts of England Probably no one would deny that in such a city as London a system of underground drainage is the best arrangement possible and is, indeed, the only one practicable It does not therefore at all follow that such a system is the best for all places and there is no doubt whatever that sufficient attention has not hitherto been given by professional sanitarians to the subject which Dr Poore has [illegible] special hobby Dr Poore sums up as the ch [illegible] what he calls his "sanitary faith" as being th [illegible] hat the protection of the purity of water-sup [illegible] effected by properly tilling the humus "I bel [illegible] organic filth [illegible] kinds should be kept [illegible] to nourish the [illegible] d not be placed be [illegible] the wells, [illegible] eve that the [illegible] eat [illegible] increase [illegible] er has been w [illegible] fouled, [illegible] uling, our [illegible] o [illegible] stically [illegible] po [illegible] its chief [illegible] "sc [illegible] enough [illegible] with a [illegible] ds as [illegible] and [illegible] ern [illegible] ly [illegible] are system " or else he must take a special-delight in the growth of cabbages, which as Dr Poore quite truly points out, grow exuberantly when dressed with night-soil.

It may be hoped that the sanitary officers in charge of the camps on Salisbury Plain will accept in good part the criticisms and will adopt the suggestions which the author gives as to the disposal of the refuse of the camps. The Wiltshire downs were lately amongst the healthiest places of England and it would be scandalous if their sanitary state should be reduced to the Aldershot standard. Dr Poore has done an undoubted and a great public service in calling attention to this question.

More than one of the shorter papers contained in this volume deserves a larger space than it is possible to give to it in a brief review We are not in accord with Dr Poore on every point , it is obvious, for example that his criticisms of the investigations on tabes mesenterica made by the late Sir Richard Thorne are open to objection. The book is an extremely suggestive one and is pleasantly written. It contains a sufficient number of illustrations to explain the text and amongst the most interesting of those are several plans of the sanitary arrangements of an experimental cottage which the author has built near Andover in Hampshire, just outside the boundaries of the borough The site was chosen to escape from possible hindrances and prohibitions " which it was thought the model by laws of the Local Government Board might cause within the area in which they were in force. The sanitarian found it wise to evade sanitary control This gives food for reflection.

LIBRARY TABLE

Atlas of Practical Elementary Zootomy By GEORGE B HOWES, LL.D F R.S. London Macmillan and Co. 24 Plates and Text. Price 10s. net.—This new edition of an atlas brought out by the author to illustrate a number of types required for many examinations differs from the first edition in that the botanical part has been entirely dropped hence the name has been altered from biology to zootomy " The drawings are largely the same, but there are alterations and additions demanded by our growing knowledge of the animals whose structure is delineated. The book is little more than an Atlas with mere explanations of the figures. The author gives as notes a considerable amount of information concerning recent research and heads the work with a brief bibliography of such treatises as will be found most useful to the student who desires not to limit himself to an elementary conception of the facts before him. The bibliography is particularly well arranged and thoroughly up to date The plates are of exactly the same standard of excellence as were those of the earlier edition, but a good many new figures have been interpolated and others have been slightly altered. The alterations and additions are for the most part upon those plates which refer to the frog and to the earthworm. It is perhaps, mainly in these two animals that recent progress has been most active and correction and addition therefore rendered essential to the learner After the most careful examination of the drawings we have not been able, as indeed was to have been expected to find any positive errors. There are, however one or two figures to which we take exception on various grounds In Fig 9 of Plate XIV the oviducal funnel of the earthworm is made to look very different from the corresponding funnels of the sperm ducts while the receptaculum ovorum which is of course a chamber containing eggs and the probable homologue of the sperm sacs is made to look rather like a funnel turned backwards. The abundant lettering which serves as a guide to the drawings will, however render any danger arising from this slight confusion quite impossible. In presenting the student with this useful aid to his studies the author naturally points out that the 30 years experience of the "Huxleyan Type System ' has been its best justification and that being the case it is right for the student to get at his facts as much as possible for himself To do so renders the subsequent lectures of more value. The volume before us should remove all difficulties from the student s path

The Royal London Ophthalmic Hospital Reports. Edited by W LANG, F R.C.S Eng Vol XV Part 2. May 1902. London J & A. Churchill 8vo pp. 106.—The articles contained in this part are 1 The Nerve Supply of the Lacrymal Gland, by J Herbert Parsons F R.C.S. Eng In the course of his observations on this subject the author considers that whilst it cannot be regarded as settled there is yet a sufficient amount of evidence in favour of the facial nerve being the secretory nerve of the lacrymal gland to cast much doubt upon the generally received view in favour of the trigeminal. Reference is made to numerous cases in which there was deficient action of the lacrymal gland with lesion of the seventh nerve. 2. A case of Sympathetic Inflammation affecting the Posterior Part of the Uveal Tract, by J Herbert Fisher F R.C S Eng 3. Cases and Observations by E. Nettleship. These include an account of some cases of temporary blindness from exposure to cold wind some cases of Berry's hyperplastic subconjunctivitis some cases of partial albinism a case of uniocular spasm of accommodation , and cases of retrobulbar optic neuritis. 4 Cases of Mesoblastic Tumours of the Orbit, by A. Quarry Silcock and C Devereux Marshall. 5 Arcus Senilis by J Herbert Parsons, curator of the Ophthalmic Hospital Museum The conclusion arrived at by Mr Parsons is that the arcus senilis is probably a peculiar form of fatty degeneration of the substantia propria of the cornea. 6. A Report of the Cases in which Haab s Magnet was Used for the Extraction of Foreign Bodies from the Eye at the Royal London Ophthalmic Hospital, by A. Ferguson MacCallan, F R.C S Eng 39 cases are reported with varying results It is shown that the removal of a foreign body from the vitreous is far more difficult and more dangerous to vision than its removal from the anterior chamber iris or lens

Laboratory Work in Histology By G CARL HUBER, M.D Junior Professor of Anatomy and Director of the University of Michigan. Third edition, revised and enlarged. Ann Arbor Michigan George Wahr 1900. 8vo pp. 204 —Every student requires a guide to histology The examination of fresh tissues, the methods of isolating fixing hardening decalcifying injecting embedding cutting and staining all require exposition and the means of accomplishing them do not come by nature. The work is divided into two parts the first describes the technique of the microscope and the methods at the disposal of the student , the second discusses the several tissues and the way in which they should be treated. The author very truthfully observes that there is a tendency at the present time to rely upon the newer and more complicated methods of research and to disregard or to belittle the rough and ready methods of the older observers. The student should, however be early led to recognise that important observations may be made with the unaided eye and with simple lenses on tissues removed for such study without further preparation and he should be particularly instructed and encouraged in the examination of fragments of tissue obtained by careful teasing out of larger pieces by means of needles and the scalpel. A better idea," he goes on to say of the shape, size and normal appearance of tissue elements can often be obtained in this way than from sections of tissues prepared after the most approved methods " with all of which we cordially agree. The following quotation of the mode of examining heart muscle will show how the author deals with each subject. 1. Isolated heart-muscle cells.—Small pieces of the cardiac muscle of a dog should be macerated in a 30 per cent. solution of caustic potash for 15 minutes, the maceration is then to be interrupted by placing the tissue in a saturated aqueous solution of potassium acetate. Tease in gum glycerine Observe the short oblong cells, one end usually branched The cells show a cross and longitudinal striation and possess one, occasionally two, oval nuclei. Draw several as seen under high power" It is to be observed that two or three blank pages are intercalated in the text on which the student may make, and thus preserve, his sketches "2. Section of heart muscle—Small pieces from the ventricles of the human heart should be fixed in Zenker's fluid, embedded in celloidin, sectioned and stained in hæmatoxylin and eosine, mounted in balsam, and studied under low and high powers Note how the cells are cemented into fibres and then into anastomosing bundles In cross sections of the muscle the nuclei are seen occupying the centre of the cells Sketch as seen under high power" The attention of the student might perhaps have been called to the absence of a sarcolemma and the size of the elements might have been mentioned. A great number of stains are given, of which may be mentioned Böhmer's hæmatoxylin solution, Mayer's acid hæmalum solution, Ehrlich's hæmatoxylin solution, Heidenhain's hæmatoxylin solution, Heidenhain's iron lack hæmatoxylin solution, Grenacher's borax carmine solution, Grenacher's alum solution, Orth's lithium-carmine solution, Orth's picro lithium carmine solution, Ozocor's alum-cochineal solution, a large number of aniline stains, Ehrlich's and Bizzozero's gentian violet solution, various modes of double staining as by van Gieson's acid fuchsin picric acid solution, Weigert's picro carmine, Rawitz orange G and hæmatoxylin, Stroebe's aniline-blue and safranin, and many others Dr Huber's book will prove a useful addition to any laboratory

Analytical Records

FROM

THE LANCET LABORATORY.

BYNO CASCADA

(ALLEN AND HANBURYS LIMITED, BETHNAL-GREEN LONDON, E.)

As the name to some extent implies this preparation is a combination of liquid malt extract (bynin) with *Rhamnus purshiana*, to which has been added *Rhamnus frangula* It appears that the addition of a certain proportion of extract of frangula bark is useful in re-establishing the aperient effect of cascara in patients who have become habituated to it. We find that the preparation is not disagreeable to the taste and it exhibits a marked digestive effect upon starch The combination is useful as a laxative, the liquid malt contributing to the action and at the same time helping the powers of digestion Whilst producing a satisfactory aperient action there is no griping effect.

ELIXIR OF THE GRANDE CHARTREUSE

(AGENCY, H. RIVIÈRE, 25 CRUTCHED FRIARS, LONDON E C)

This elixir has an origin and history resembling that of the celebrated liqueur of the Grande Chartreuse The recipe, it is stated, was given in 1607 to the Chartreuse of Paris, but the monks of this monastery, owing to the difficulty of procuring the Alpine plants, handed it over to the Grande Chartreuse in 1735 Later "the brother Jèrome Maubec, qualified by a manuscript of the time as a very skilful apothecary, modified and brought to perfection the first formula." The elixir presents the same colour as the so-called green Chartreuse and when examined by the spectroscope exhibits absorption bands peculiar to chlorophyll. So far as our examination has gone we were not able to trace any but vegetable colouring matters. Our analysis gave the following results alcohol, by weight 52 23 per cent, by volume 60 07 per cent., equal to proof spirit 100 27 per cent. , residue, chiefly sugar, 11 29 per cent ; and mineral matter, 0 03 per cent The elixir gives an agreeable sensation of warmth in the stomach and the aromatic oils present serve as carminatives. On this account the elixir has been used in indigestion and flatulence, while it is regarded also as a cardiac tonic and febrifuge

COCOA POWDER

(A DRIESSEN, ROTTERDAM DE BEER BROTHERS AND COMPANY, 28, MINORIES, LONDON, E C)

The features of this preparation calling for remark are its excellent flavour and degree of solubility The results of the analysis, which are normal, were as follows moisture, 3 98 per cent , mineral matter, 6 42 per cent. , alkalinity reckoned as potash, 2 54 per cent , and fat, 34 80 per cent The particular method of preparation of this cocoa is calculated to render it easily assimilable and digestible, while the aroma and flavour characteristic of good cocoa are preserved

EVIAN (SOURCE CACHAT) WATER

(AGENCY, E GALLAIS AND CO , LIMITED, 90, PICCADILLY, LONDON W)

Evian-les-Bains is picturesquely situated in the Upper Savoy on the Lake of Geneva opposite to Lausanne The water is remarkable for its organic purity It contains trifling amounts of carbonate of soda, common salt, and carbonate of lime. The total mineral contents, according to our analysis, do not exceed 23 grains per gallon and these consist chiefly of carbonate of soda with a little salt and calcium carbonate. The water is used for its diuretic properties A continued course of the water is said to favour the action of the digestive processes and to be an advantage in hepatic disorders

VARIOUS SOAPS

(J F MACFARLAN & CO EDINBURGH AND 9, AND 11, MOOR LANE, FORE-STREET, LONDON, E C)

These soaps give evidence of careful preparation and the choice of special ingredients both for the soap basis and for the medicament. According to our examination the soaps are superfatted and it is stated that the fats used for the purpose are edible We could find no evidence of alkaline excess or of the presence of irritants The specimens were as follows lysol 5 per cent , ichthyol 15 per cent., carbolic acid 10 per cent , lanoline and "cream skin" soap The last two are very pleasant to use, giving a smooth creamy lather without waste

ODOL

(ODOL CHEMICAL WORKS 26, SOUTHWARK BRIDGE ROAD, LONDON, S E)

Odol is intended as an antiseptic mouth-wash and consists, according to our examination, of a spirituous, fluid turning milky on the addition of water The milkiness proved to be due to the presence of an oil, a definite compound of phenol, and salicylic acid The two constituents are easily separated on saponification by soda. Odol is powerfully antiseptic and forms an agreeable and effective mouth wash It possesses a smell recalling oil of peppermint

NOBES DISINFECTANT

(THE NOBES DISINFECTANT CO AGENCY CAMPBELL, SHEARER, AND CO., 4 EASTCHEAP LONDON, E C)

The most powerful germicide known is probably formaldehyde which is the most important constituent of this disinfectant fluid. The fluid is pink in colour and exhibits a slight fluorescence. On evaporation to dryness a solid residue was obtained amounting to a little over 1 per cent. This residue evolved formaldehyde when heated. The preparation is, of course, not only an effective germicide but a deodorant also Moreover formaldehyde may be successfully used for aerial disinfection.

TABLOID" LITHIUM CITRATE AND SODIUM SULPHATE (EFFERVESCENT)

(Burroughs Wellcome, and Co, Snow Hill-buildings London E.C)

The tabloid lithium citrate and sodium sulphate is of about the size of a shilling piece but of three times the thickness. When placed in water it dissolves with abundant disengagement of carbonic gas, yielding a medicinal and refreshing draught. The combination of a small dose of a saline purgative with lithium citrate is obviously called for in some conditions. One tabloid contains 30 grains of sulphate of soda and five grains of citrate of lithium.

PAUTAUBERGE SOLUTION (CHLORHYDRO-PHOSPHATE OF LIME AND CREASOTE)

Agency: Wilcox and Co 49 Haymarket London S W

This combination of creasote with phosphate of lime and hydrochloric acid has been proposed for the treatment of bronchial catarrh and pulmonary tuberculosis and instances are cited in which while creasote could not be tolerated or else did little good this form gave favourable results. Pautauberge solution is of the colour of a dilute solution of perchloride of iron with a marked taste and odour of creasote. On the addition of an alkali such as ammonium hydrate the calcium phosphate is precipitated Good results in various affections of the respiratory organs are recorded in French clinics. The preparation is a decided pharmaceutical success in presenting creasote in a far less objectionable form than is commonly the case and its association with tonics is another advantage

BERI BERI

PROFESSOR UCHERMANN'S VIEWS.

AT a meeting of the Norwegian Scientific and Literary Society held at Christiania on May 30th Professor Uchermann gave an account of the results of the investigations of the committee appointed for the consideration of Beri Beri and showed that the problem had been solved as far as was possible until the poison itself was determined He briefly noticed the distribution of the disease its pathological anatomy and the supposed causes—causes which might be classed under the two heads indirect or disposing and direct or initiating both however being equally doubtful and unproved. He then mentioned the various theories founded thereon the most important of which were the following (1) that beri beri was an infectious disease due to a specific microbe (2) that it was a constitutional disease due to inadequate or physiologically insufficient food, especially the want of azote (albuminates) and fat, and (3) that it was due to an intoxication through the food some considering it a rice intoxication and others a fish intoxication those articles undergoing chemical changes possibly through the action of micro organisms. Others considered it to be an auto-intoxication the ptomaines of the food and of the intestinal canal being absorbed while yet others thought that it was an intoxication due to the presence of inorganic poisons, especially arsenic, in the food. None of these theories explained in a satisfactory way the appearance in late years of the disease in Europe and especially on European sailing ships Norwegian among the number Hitherto there had not been placed before the public any collective material from which to judge of the causes of beri beri on ships but only isolated cases that had been criticised from the standpoint of the more varied experience drawn from India, Japan and Java.

The material before the committee was based on the replies to certain questions made through consuls or received by members of the committee from master mariners and sailors, the information being obtained from 104 ships in all These facts enabled a person for the first time critically to weigh the various views that could be entertained concerning the causes of beri beri in ships It was evident (1) that the general opinion in dating the appearance of beri-beri on Norwegian ships to the last decade of the late century and its especial prevalence after the year 1895 was correct (2) that the Norwegian ships and as far as the small number allowed a conclusion to be drawn Scandinavian and Finnish ships were most attacked the German ships coming next in the proportion of cases, while the English ships suffered very little (3) that the disease appeared to be most common on sailing ships (of the 104 ships attacked there was but one steamer and that had one patient), (4) that the great majority of the opinions expressed tended to the belief that inadequate food and especially much tinned food directly produced beri beri or indirectly furthered it, (5) that the drinking water could not be the cause of it, (6) that the disease had appeared on ships where rice had neither been used nor had been on board at all (7) that the partaking of tinned food was not necessarily followed by an appearance of want of nourishment in the patient (8) that lime juice was not a sure prophylactic against beri beri, though it might exercise a certain preventive influence against the disease or occasionally a favourable influence on its course (9) that the foregoing conclusion held good also with regard to fruit and fresh vegetables especially potatoes (10) that beri beri appeared on sailing ships on long voyages though they had departed from a region free from beri beri (this was the case with 10 ships) and though the disease had not previously appeared on board nor the crew previously had the disease (11) that there was no indication of any rule for the time of the incubation of the disease, such time varying from the first to the 120th day after leaving port (12) that the hydropic form of the disease was the most common in the ships (only three or four cases of the atrophic form were mentioned) while in Japan it hardly amounted to one-half the cases, (13) that the disease was afebrile, (14) that animals were also attacked (15) that in several cases vomiting appeared at the very beginning of the disease but stopped immediately the patients went on board another ship and got different food, (16) that generally speaking fresh provisions in the form of meat fruit, and fresh vegetables in a short time cured the disease in the vast majority of cases, when it was not too far advanced, and (17) that symptoms resembling scurvy did not appear

After a critical examination of the theories Professor Uchermann concluded that beri beri was the Oriental name of multiple neuritis and was due to a toxin intoxication by tainted vegetable or animal food The vegetable form closely corresponded with the Asiatic beri beri and was usually owing to the eating of tainted rice. The animal form corresponded particularly with the beri beri which appeared on European sailing ships and was due chiefly to the eating of tainted tinned food. It might indeed be supposed that the beri beri poison might appear not only in vegetable but also in animal nitrogenous food stuffs that were or had been undergoing decomposition of a microbic nature as yet undecided These microbes were probably not specific, and in all likelihood were different in the animal and vegetable forms of the disease. Nor need the poisons themselves from a theoretical point of view be absolutely identical in both forms even if they were in all probability homogeneous and in some degree isodynamic. As to the importance of lime juice, potatoes &c. it might be supposed that the vegetable acids contained in these articles of food entered into compounds with the toxins generally basic, rendering them innocuous or making them more easily secreted In accordance with these conclusions the committee advised (1) a restriction in the use of tinned food (according to French investigations of the various kinds of tinned food from 70 to 80 per cent. contained viable microbes) (2) that fat should be made a component part, even if a limited part, in the scale of diet in warm climates (3) that potatoes and fresh vegetables should be provided for the whole voyage, ships being provided with a better system of preserving these articles (4) that fresh fruit and fresh provisions should be used during the stay in port (5) that on long voyages the quantity of sugar and dried fruit should be increased and (6) that on long voyages the use of a water filter (Chamberland Pasteur) should be enjoined. In addition the committee gave careful directions as to the quality purchase preservation and final packing of the provisions (the food being inspected when purchased and afterwards once a fortnight) and directions as to how to act should beri beri scurvy or similar food diseases appear at sea (the nearest port to be sought.) Finally lime juice was enjoined on voyages south of 33 S if the potatoes should run short.

which hospital physicians might easily come to a common understanding

The cases of small pox treated during the period reported on were 1810 in number Of these patients no less than 1643 had been vaccinated, while 45 were doubtful, and 122 were unvaccinated Dividing the "doubtfuls" equally among the vaccinated and unvaccinated the latter amount to about 8 per cent. of the total cases. In Glasgow primary vaccination is so general that only 3 or 4 per cent. of the population are omitted, and the "crude" result appears to be that the 3 or 4 per cent contributed about 8 per cent. of the small-pox. So far as it goes, that is as might be expected, and there is an easy explanation of the unvaccinated not having contributed a much larger percentage of the total admissions than these figures indicate It is to be found in the ages of the vaccinated patients Of 1643 only 3 were below the age of five years, only 31 between five and ten years, and only 93 between ten and fifteen years. It is in the adult ages that we find the great numbers of vaccinated cases admitted to Belvidere Hospital. Of the total 1643 patients no less than 627 were between 25 and 35 years old None of these had been revaccinated and their protection against attack by small pox had largely disappeared, though it still remained very effective against death by small-pox. But there is a further and a most unsatisfactory explanation of the percentage of vaccinated admissions In the 1643 cases 886 had only one mark of vaccination and 589 had two marks, while only 94 had three and 74 had four marks. Abundant recorded experience of small pox and vaccination makes it safe to assume that the well vaccinated yield much fewer small-pox cases in proportion to their numbers than the imperfectly vaccinated, and the above figures show that there is far too much one- and two-mark vaccination in Glasgow So long as this is the case, and the inefficient primary protection is not supplemented by revaccination, small pox outbreaks will find many victims among the vaccinated.

The fatality of the disease in Belvidere Hospital shows the usual discrimination between vaccinated and unvaccinated, the respective rates being 9 13 per cent. and 51·64 per cent It is suggested in the paper that the fatality rates of pre vaccination times included inoculated small pox. That is very doubtful, but it is quite true, as also urged in the paper, that trustworthy statistics of fatality rates on a large scale for early times are very scanty It might have been added that the best known of these old rates cover only a limited period of time and do not distinguish ages Obviously also the fatality of some infectious diseases varies greatly as between one time and another and one place and another, while in small pox, whatever be the gross fatality, that of the vaccinated is always much less than that of the unvaccinated, age for age. In Belvidere Hospital, among 258 vaccinated patients under 20 years old there were two deaths, and among 86 unvaccinated patients under 20 years old there were 44 deaths. These latter, however, may have included some babies under six months One fact which should appeal to a Scotch town council's sense of economy is given in the paper Of cases which recovered the average residence of the vaccinated was 29 days in hospital and of the unvaccinated 56 days, the relative cost per case being £6 10s 6d and £12 12s

The Belvidere Hospital staff, being revaccinated, experienced that immunity from small pox which though so familiar is none the less remaarkble. As usual, also, there were certain unintentional or unavoidable control experiments Of six revaccinated vanmen regularly bringing supplies to the hospital none took small-pox, "but on one occasion a substitute who had not been revaccinated was sent in place of one of these. This man paid only one visit to the hospital and was admitted a fortnight later with small-pox " Of 230 workmen employed to erect temporary pavilions 217 were successfully revaccinated and all escaped small pox, while 13 refused or escaped revaccination, and of these five contracted small pox and one died. It is sometimes alleged by opponents of vaccination that the immunity of small pox nurses is due to their being accustomed to such work That is amply disproved by the way in which they succumb to other infectious diseases Here however no such sophistry, worthless as it is, can be brought forward. Let it be observed that the 230 were not nurses habituated to hospital work, but were introduced from the outside for a purely temporary purpose. The revaccinated nurses, it need hardly be added, also remained free from small pox. In conclusion, there is one point which we would suggest to the authors of the paper for further research, or at least for further report. It seems from page 20 that, in revaccinating, what amounts to Bryce's test, so well known in JENNER'S time, was regularly practised. A record of the results would be interesting and valuable

◆

Juries and Actions for Malpraxis

WE find published in the *Canada Lancet* for June a full report of an interesting and instructive judgment delivered, in an action for alleged malpraxis, by the Hon W G FALCONBRIDGE, Chief Justice of the King's Bench, Ontario It is instructive because it deals exhaustively with the facts before the learned judge and with the law applicable to them, and not the least interesting point in connexion with it is a declaration of the practice prevailing in the Canadian courts with regard to this class of action The action was brought by the wife of a farmer against two medical men practising in partnership, on the ground that they had negligently, improperly, and unskilfully treated her for injuries to her foot and ankle, the result of a fall, so that her foot was distorted and twisted and she was rendered permanently lame, with consequent additional injury to her general health. With regard to the legal practice in such cases the learned judge observed as follows "Actions of this kind were, as a matter of course, formerly tried, both here—i.e., in Canada—and in England, by a jury, and it was the almost inevitable result that juries, perhaps innocently and unconsciously, looked more favourably upon the case presented by the patient than on that presented by the physician or surgeon. To remedy this condition of affairs, and not to leave doctors entirely at the mercy of juries, the courts of this country early became astute to lay down limitations and restrictions on the actions of the Twelve, or rather as to what matters ought to be left to them to deal with For example, in 1889 the Court of Queen's Bench held in

JACKSON v HYDE, 28 U C R 294 that in an action against a surgeon for negligent malpractice, where the evidence is as consistent with the absence as with the existence of negligence, the case should not be left to the jury " It is upon this aspect of the case and not upon the purely surgical questions of diagnosis in reference to injuries about the ankle joint that we propose to comment

There must be evidence from which negligence may reasonably be inferred before a case is left to a jury to deal with in England as well as in Canada, but the observations of Chief Justice FALCONBRIDGE point to a withdrawal of cases from Canadian juries which in England would be left to them such withdrawals being apparently to some extent due to the influence rather than to the authority of the judge. The opinions of Canadian judges with regard to juries appear to be expressed with considerable candour When an English judge rebukes a jury for a perverse and obviously unjust verdict in a case which he may nevertheless have been compelled to leave to their decision he is usually made the subject of unfavourable comment by newspapers ignorant of the circumstances, although newspapers curiously enough are frequently themselves victims of verdicts which in their own cases they would protest against if it were possible safely to do so One of the judges in JACKSON v HYDE the Canadian case referred to said however —and we believe that he put the matter truthfully and temperately It is notorious that there are many cases in which jurors are not the most dispassionate or most competent persons to try the rights of parties and an action of this kind (against a surgeon for malpraxis) comes within the class to which I have alluded In England, however the plaintiff in such actions as we are referring to may always ask for a jury and we are not aware that his request is ever refused nor do we blame him for demanding the tribunal which is most likely to find in his favour In Canada it appears to be left to the discretion of the judge to put pressure on the parties to try the case before him alone, for in the case on which we are commenting Chief Justice FALCONBRIDGE states that he tried the issues without a jury both parties having consented to his doing so. The matter was left in thoroughly good hands

In this case it was proved that one of the partners sued had with another surgeon attended the plaintiff who had recently injured her ankle. The evidence of these two gentlemen was to the effect that they had set a fracture the precise nature of which the report does not clearly show, and had reduced a dislocation of the astragalus while their treatment, particularly with regard to the method of bandaging and keeping the ankle in position was approved by three surgeons who gave evidence on their behalf A surgeon appointed by order of the court, a practice not used in England reported to the effect that at the time when he made his examination the astragalus was not in its normal position that there was no sign of there ever having been any fracture of the tibia or fibula, and that though the pain in using the foot might diminish the deformity caused by the dislocation would be permanent On the side of the plaintiff evidence was given by two medical witnesses that, if it were granted that the injury was correctly diagnosed the treatment was improper There was direct affirmative evidence called by the defendants including that of two women friends of the plaintiff, that the plaintiff herself had at an early stage tampered with the bandages and that these were loosened by her to such an extent that the dislocation, undoubtedly still existing might by these means have taken place In these circumstances there was a case such as in England would have been left to a jury to decide and the Canadian judge is to be congratulated on having dispensed at the outset with the aid of twelve men of varied intelligence and experience and on having relied upon himself seeking apparently a responsibility which many English judges accustomed to juries would do their best to avoid. The judgment delivered by Chief Justice FALCONBRIDGE, thoughtfully prepared and carefully reasoned concluded by entirely acquitting the defendants of blame, and contained passages relating to matters of evidence the full weight of which many jurors would have failed to appreciate. In fact, the case was one in which a verdict might easily have been given for the plaintiff, in defiance of justice by many well meaning juries.

It was for example, urged on behalf of the plaintiff that there had been a wrong diagnosis and that no fracture had ever existed this being supported by evidence that the x rays revealed none. We have pointed out that when a sufficient time has elapsed for the callus to have become absorbed no change of outline need remain capable of being revealed easily by a skiagram where a fracture has taken place and been accurately reduced. In the case in point the injury took place nearly three years before the trial and two years before the x rays were applied. That a surgeon should imagine a fracture and ignore a dislocation would seem natural to a jury impressed by the dislocated ankle admittedly before the Court and the fact that it would render the plaintiff lame for life The reasons making such an error highly improbable, together with the full import of the patient's own interference and the comparative weight of the evidence of surgeons of varying degrees of professional eminence and opportunities for forming their opinions are, on the other hand matters far more likely to be properly considered and dealt with by a judge The judge also can reserve his decision and deliver it without haste, after the eloquence of counsel has been to some extent forgotten basing it upon a minute and thoughtful study of the evidence. It must be remembered that however fully the judge may grasp the points of a case and however clearly he may indicate the right course to a jury he may still be unable to overcome prejudices and to guide a verdict. A jury may even seek to show its British independence by going against the recommendation of the judge who in his desire to secure justice for a suitor has to exercise the nicest tact and the most ingenious methods of persuasion in order to avoid if possible, rousing suspicion and opposition and so defeating his own object.

An action tried before Mr Justice CHANNELL and a special jury at the recent assizes at Nottingham suggests many points of interest to medical men which we cannot discuss in detail without a fuller report of the evidence than we have at present seen It appears however to have been decided upon evidence in many respects closely resembling that given in the Canadian case which we have just discussed.

THE LANCET.

LONDON SATURDAY, JULY 26, 1902

The Annual Meeting of the American Medical Association

WE received through the courtesy of more than one of our brother editors in the United States advance proofs of many of the addresses delivered in connexion with the fifty-third annual session of the American Medical Association, but until this comparatively late date we have been unable to find an opportunity of giving them the attention that they merit. The presidential address was delivered on June 10th by Dr JOHN ALLEN WYETH of New York. It dealt with many subjects, for the orator passed in review most of the matters which have concerned the medical profession in the United States during the past year. In many of these subjects the medical profession in this country is equally interested. The Medical Department of the United States Army suffers like our own Royal Army Medical Corps in being insufficiently manned. The prospects of promotion, too, are far from good. Dr WYETH rightly urges the importance of the American Medical Association, as the representative organisation of the medical profession in the United States, coöperating with the medical corps of the army in the effort to procure legislation which will not only uphold the rights and dignity of the medical officers in the public service, but will give better protection to the health and lives of the troops. Within the last few years the medical profession in the United States has had to contend with a wide dissemination of the contagion of small pox. The neglect of vaccination in that country, where no law for compulsory vaccination has yet existed, has led to results not very different from those obtaining in the British Isles where laws once compulsory have been so whittled down as to have lost practically nearly all their compulsory powers. Dr WYETH considers compulsory vaccination in the United States to be impolitic and impracticable, but hopes for an extension of vaccination from the labour of physicians in impressing on the community the necessity and safety of this immunising process. The American Medical Association aims to raise the general level of medical education in the United States and also to improve the general status of the profession. It claims to represent 120,000 practitioners of medicine and its efforts should prove fruitful of good not merely to the medical profession itself but also to the people in general. Much has been done within recent years, but still much remains to be done, and the association will deserve well of the profession in all parts of the world if it succeeds in realising its high educational and ethical ideals.

The address in Medicine was delivered by Dr FRANK BILLINGS of Chicago, and the subject was the Relation of Medical Science to Commerce. He pointed out that medicine is of greater importance to the world than ever before in protecting individuals, communities, and nations from infectious diseases which are more dangerous than formerly because of a denser population, increased facilities of communication, and international interchange of food and other products. Medicine has to safeguard man against infection from parasitic diseases of the animals used for food and against contaminated and adulterated food. Dr BILLINGS asks, "Is modern medicine prepared to meet the demands of modern progress?" and he answers the question by showing what medicine has done in the past century and what it is prepared to do if called upon. He showed the vast results which have followed the study of bacteriology which was only made possible by the development of the microscope. The cultural methods of KOCH have made bacteriology an exact science, and they first rendered possible the separation and differentiation of bacteria. The mode of transmission of infection is especially important. Dr BILLINGS pointed out that the rôle played by insects in the transference of micro organisms has been studied and proved, and that the etiology of malaria and yellow fever has been made clear. By the microscope we can recognise malaria and differentiate it from other febrile diseases; nay, more, we can recognise the type of malarial infection and foretell its course. The first example of protection afforded by the inoculation of an attenuated virus was provided by vaccination against small pox, and this method is now firmly established for some other diseases also. The introduction of serum therapy has been a further step in the treatment and prevention of disease and the method has been specially useful in diphtheria. The prevention of infection in the lower animals is of the greatest importance to man, and with our present knowledge of the bacteriology of disease it would be possible to stamp out any microbic disease of the lower animals. The destruction of the infected bodies of animals is often necessary and this may imply loss to the individual or the community, but this temporary loss would prove to be a permanent gain to the whole people. Dr BILLINGS showed how the application of the knowledge of the transmission of yellow fever by means of the mosquito, demonstrated by REED and CARROLL in Cuba, has had immediate practical results. In Havana during 1901 attempts were made by the sanitary authorities to test the mosquito theory of transmission. The city was made clean; the breeding places of the mosquito in and around the city were destroyed as far as possible, and persons suffering from yellow fever were isolated and protected from the mosquito. As a result yellow fever disappeared from Havana and for the first time for years no case had occurred up to May 1st of this year. This freedom from yellow fever removed the necessity for quarantine regulations against ships from Havana and thus a distinct pecuniary saving was effected by medical science. The mosquito is of equal importance in the transmission of malaria, and experiments have shown that non immune persons may live safely in the most malarious districts if simple precautions are taken against the bites of this insect. The value of medical knowledge to the commercial interests of the world is not adequately recognised. Dr BILLINGS'S address concluded with an appeal on behalf of medicine for the moral and financial support of public bodies in the employment of the measures which science had proved to be efficacious in modifying restricting and *abolishing infectious disease. Original research should be* endowed and funds should be provided for the support of investigators in regions now dangerous to the white man.

It is right, therefore, that medical science should demand of the monied *interests of the world the recognition* which, though long withheld is her just due. This she asks not that individuals may profit in either fame or fortune but that she may the more readily rid the world of infectious diseases for the sake of humanity

The opening address in the Surgery Section was delivered by Dr HARRY M. SHERMAN of San Francisco who took for his subject the Suture of Heart Wounds. A most interesting table from this paper is published in this issue on p 233. It is not long since the idea of interfering surgically with *the heart would have been looked upon as utterly absurd* yet when at last an attempt was made to close a wound of the heart it was found that the heart, like many other organs, more readily endured interference than was imagined to be possible. Some years ago ERICHSEN said that in his opinion surgery had nearly reached its final limits and that there must be portions of the human frame that will ever remain sacred" from the intrusion of the surgeon. It is always difficult to foresee the direction in which advance will be made though those advances appear most simple and obvious after they have occurred. Since ERICHSEN wrote surgery has made many and great advances and it is difficult to be sure that no further extension of the field of its activity can occur Until 1896 however the heart had remained untouched, but in that *year an Italian surgeon (FARINA)* succeeded in placing three sutures in the wall of a right ventricle which had been perforated by a stab. The patient died, but not until the sixth day and the cause of death was broncho pneumonia. So that so far as the heart suture itself is concerned this case may be looked upon as a success. The example thus set was soon followed Two other cases were recorded in the same year two in 1897 four in 1898, eleven in 1899 three in 1900 and nine cases in 1901 whilst this year two cases have already been reported. So that up to the present 34 instances of the suture of heart wounds have been placed on record. These provide sufficient material to enable a very definite idea to be formed of the conditions which govern success. Of the 34 patients 13 ultimately recovered—a result which may be looked upon as very satisfactory when we consider the importance of the organ involved. In all but two cases the injury was caused by a stab, in the two exceptions it was due to a bullet The ventricles are much more likely to be injured than are the auricles, for in only two cases was an auricle *implicated* and this is fortunate, for it is far easier to insert sutures in the thick walls of the ventricles than in the far thinner walls of the auricles. Some of the earlier operators held that it was advisable to insert and to tie the sutures during the *diastole of the heart.* At first sight this might seem advisable but, as Dr SHERMAN pointed out a little consideration will show that it is practically impossible for the heart is beating rapidly probably at least 100 times a minute, the interval between two beats is so extremely short that even the most skilful surgeon could not insert a stitch in the time. It is as well not to penetrate the endocardium but this fortunately is not at all easy in the case of the ventricles. The material of the suture appears to be unimportant silk has been chiefly used, but in several cases catgut has been employed with success Interrupted and continuous sutures have been tried and the only difference appears to be that the continuous suture can be applied a little more rapidly

The heart resents interference much less than might have been expected, though if the edge of the heart wound be held with forceps the heart may contract more violently on account of the local stimulation. The chief point of difference between the suture of the heart and of ordinary skeletal muscle is that the latter can be kept at rest during healing while the heart must still continue to contract more than 70 times a minute Suture of wounds of the heart must be judged by results and the 13 successful cases that we have already mentioned prove conclusively that the operation is good and it may now be definitely laid down that when the heart is wounded an attempt should be made to close the wound. Of course it frequently must happen that the loss of blood is so great and rapid that death occurs before a suture can be applied. In fact, of the 34 cases recorded five patients died on the operating table and 10 very soon afterwards from the effects of hæmorrhage and shock so that for a correct appreciation of the value of the operation we may not unreasonably exclude these thereby raising greatly the percentage of recoveries Up to the present the application of sutures to a wounded heart is the only operation that has been undertaken but it would be unwise to declare that surgery will attempt nothing more in connexion *with the heart* A *note by* Sir LAUDER BRUNTON published in our columns on Feb. 8th, 1902, suggested the possibility that the grave effects of stenosis of the mitral valve might be relieved by surgical division of the diseased valve but as yet there is not much evidence before the medical profession that good would follow such a heroic proceeding We felt it our duty to disapprove of the suggestion, but we willingly admit that at present surgeons cannot see what is really practicable and what is not. Time must be allowed to play its usual part

Small-pox in Belvidere Hospital

DR. R. S THOMSON and Dr R. FULLARTON have reprinted a paper contributed by them to the Transactions of the Royal Philosophical Society of Glasgow giving an account of small pox in Belvidere Hospital Glasgow from April 10th, 1900 to June 30th 1901 From beginning to end the paper is brimful of most interesting material illustrated by well informed and thoughtful comment. Though addressed to a lay audience every part of it is medically valuable and not the least so the preliminary explanation of the exact sense in which well known terms— discrete confluent foveated " doubtfully vaccinated and so *forth*—are used at Belvidere. It is, indeed most desirable that throughout the country and especially in hospital work, there should be uniformity in the application of such words and phrases so that outbreaks of small pox in their relation to vaccination might be more exactly compared with each other than is possible at present. These are matters with regard to which hospital physicians might easily come to a common understanding.

The cases of small pox treated during the period reported on were 1810 in number. Of these patients no less than 1643 had been vaccinated, while 45 were doubtful, and 122 were unvaccinated. Dividing the "doubtfuls" equally among the vaccinated and unvaccinated the latter amount to about 8 per cent. of the total cases. In Glasgow primary vaccination is so general that only 3 or 4 per cent of the population are omitted, and the "crude" result appears to be that the 3 or 4 per cent contributed about 8 per cent. of the small pox. So far as it goes, that is as might be expected, and there is an easy explanation of the unvaccinated not having contributed a much larger percentage of the total admissions than these figures indicate. It is to be found in the ages of the vaccinated patients. Of 1643 only 3 were below the age of five years, only 31 between five and ten years, and only 93 between ten and fifteen years. It is in the adult ages that we find the great numbers of vaccinated cases admitted to Belvidere Hospital. Of the total 1643 patients no less than 627 were between 25 and 35 years old. None of these had been revaccinated and their protection against attack by small pox had largely disappeared, though it still remained very effective against death by small pox. But there is a further and a most unsatisfactory explanation of the percentage of vaccinated admissions. In the 1643 cases 886 had only *one mark of vaccination* and 589 had *two marks*, while only 94 had three and 74 had four marks. Abundant recorded experience of small pox and vaccination makes it safe to assume that the well vaccinated yield much fewer small-pox cases in proportion to their numbers than the imperfectly vaccinated, and the above figures show that there is far too much one- and two-mark vaccination in Glasgow. So long as this is the case, and the inefficient primary protection is not supplemented by revaccination, small pox outbreaks will find many victims among the vaccinated.

The fatality of the disease in Belvidere Hospital shows the usual discrimination between vaccinated and unvaccinated, the respective rates being 9·13 per cent. and 51·64 per cent. It is suggested in the paper that the fatality rates of pre vaccination times included inoculated small pox. That is very doubtful, but it is quite true, as also urged in the paper, that trustworthy statistics of fatality rates on a large scale for early times are very scanty. It might have been added that the best known of these old rates cover only a limited period of time and do not distinguish ages. Obviously also the fatality of some infectious diseases varies greatly as between one time and another and one place and another, while in small pox, whatever be the gross fatality, that of the vaccinated is always much less than that of the unvaccinated, age for age. In Belvidere Hospital, among 258 vaccinated patients under 20 years old there were two deaths, and among 86 unvaccinated patients under 20 years old there were 44 deaths. These latter, however, may have included some babies under six months. One fact which should appeal to a Scotch town council's sense of economy is given in the paper. Of cases which recovered the average residence of the vaccinated was 29 days in hospital and of the unvaccinated 56 days, the relative cost per case being £6 10*s* 6*d* and £12 12*s*.

The Belvidere Hospital staff, being revaccinated, experienced that immunity from small-pox which though so familiar is none the less remaarkble. As usual, also, there were certain unintentional or unavoidable control experiments. Of six revaccinated vanmen regularly bringing supplies to the hospital none took small-pox, "but on one occasion a substitute who had not been revaccinated was sent in place of one of these. This man paid only one visit to the hospital and was admitted a fortnight later with small-pox." Of 230 workmen employed to erect temporary pavilions 217 were successfully revaccinated and all escaped small-pox, while 13 refused or escaped revaccination, and of these five contracted small pox and one died. It is sometimes alleged by opponents of vaccination that the immunity of small pox nurses is due to their being accustomed to such work. That is amply disproved by the way in which they succumb to other infectious diseases. Here however no such sophistry, worthless as it is, can be brought forward. Let it be observed that the 230 were not nurses habituated to hospital work, but were introduced from the outside for a purely temporary purpose. The revaccinated nurses, it need hardly be added, also remained free from small pox. In conclusion, there is one point which we would suggest to the authors of the paper for further research, or at least for further report. It seems from page 20 that, in revaccinating, what amounts to Bryce's test, so well known in JENNER'S time, was regularly practised. A record of the results would be interesting and valuable.

◆

Juries and Actions for Malpraxis

WE find published in the *Canada Lancet* for June a full report of an interesting and instructive judgment delivered, in an action for alleged malpraxis, by the Hon W G FALCONBRIDGE, Chief Justice of the King's Bench, Ontario. It is instructive because it deals exhaustively with the facts before the learned judge and with the law applicable to them, and not the least interesting point in connexion with it is a declaration of the practice prevailing in the Canadian courts with regard to this class of action. The action was brought by the wife of a farmer against two medical men practising in partnership, on the ground that they had negligently, improperly, and unskilfully treated her for injuries to her foot and ankle, the result of a fall, so that her foot was distorted and twisted and she was rendered permanently lame, with consequent additional injury to her general health. With regard to the legal practice in such cases the learned judge observed as follows. "Actions of this kind were, as a matter of course, formerly tried, both here—i.e., in Canada—and in England, by a jury, and it was the almost inevitable result that juries, perhaps innocently and unconsciously, looked more favourably upon the case presented by the patient than on that presented by the physician or surgeon. To remedy this condition of affairs, and not to leave doctors entirely at the mercy of juries, the courts of this country early became astute to lay down limitations and restrictions on the actions of the Twelve, or rather as to what matters ought to be left to them to deal with. For example, in 1869 the Court of Queen's Bench held in

JACKSON v HYDE, 28 U C R 294 that in an action against a surgeon for negligent malpractice, where the evidence is as consistent with the absence as with the existence of negligence the case should not be left to the jury' It is upon this aspect of the case and not upon the purely surgical questions of diagnosis in reference to injuries about the ankle joint that we propose to comment.

There must be evidence from which negligence may reasonably be inferred before a case is left to a jury to deal with in England as well as in Canada but the observations of Chief Justice FALCONBRIDGE point to a withdrawal of cases from Canadian juries which in England would be left to them such withdrawals being apparently to some extent due to the influence rather than to the authority of the judge. The opinions of Canadian judges with regard to juries appear to be expressed with considerable candour. When an English judge rebukes a jury for a perverse and obviously unjust verdict in a case which he may nevertheless have been compelled to leave to their decision he is usually made the subject of unfavourable comment by newspapers ignorant of the circumstances although newspapers curiously enough are frequently themselves victims of verdicts which in their own cases they would protest against if it were possible safely to do so. One of the judges in JACKSON v HYDE, the Canadian case referred to said however —and we believe that he put the matter truthfully and temperately It is notorious that there are many cases in which jurors are not the most dispassionate or most competent persons to try the rights of parties, and an action of this kind (against a surgeon for malpraxis) comes within the class to which I have alluded. In England, however the plaintiff in such actions as we are referring to may always ask for a jury and we are not aware that his request is ever refused nor do we blame him for demanding the tribunal which is most likely to find in his favour In Canada it appears to be left to the discretion of the judge to put pressure on the parties to try the case before him alone, for in the case on which we are commenting Chief Justice FALCONBRIDGE states that he tried the issues without a jury both parties having consented to his doing so The matter was left in thoroughly good hands.

In this case it was proved that one of the partners sued had with another surgeon attended the plaintiff who had recently injured her ankle. The evidence of these two gentlemen was to the effect that they had set a fracture the precise nature of which the report does not clearly show and had reduced a dislocation of the astragalus, while their treatment, particularly with regard to the method of bandaging and keeping the ankle in position was approved by three surgeons who gave evidence on their behalf A surgeon appointed by order of the court, a practice not used in England reported to the effect that at the time when he made his examination the astragalus was not in its normal position that there was no sign of there ever having been any fracture of the tibia or fibula, and that though the pain in using the foot might diminish the deformity caused by the dislocation would be permanent On the side of the plaintiff evidence was given by two medical witnesses that if it were granted that the injury was correctly diagnosed the treatment was improper There was direct affirmative evidence called by the defendants, including that of two women friends of the plaintiff that the plaintiff herself had at an early stage tampered with the bandages and that these were loosened by her to such an extent that the dislocation, undoubtedly still existing might by these means have taken place In these circumstances, there was a case such as in England would have been left to a jury to decide and the Canadian judge is to be congratulated on having dispensed at the outset with the aid of twelve men of varied intelligence and experience and on having relied upon himself, seeking, apparently a responsibility which many English judges accustomed to juries would do their best to avoid. The judgment delivered by Chief Justice FALCONBRIDGE, thoughtfully prepared and carefully reasoned concluded by entirely acquitting the defendants of blame, and contained passages relating to matters of evidence the full weight of which many jurors would have failed to appreciate In fact, the case was one in which a verdict might easily have been given for the plaintiff in defiance of justice by many well meaning juries.

It was for example, urged on behalf of the plaintiff that there had been a wrong diagnosis and that no fracture had ever existed this being supported by evidence that the x rays revealed none. We have pointed out that when a sufficient time has elapsed for the callus to have become absorbed no change of outline need remain capable of being revealed easily by a skiagram where a fracture has taken place and been accurately reduced. In the case in point the injury took place nearly three years before the trial and two years before the x rays were applied. That a surgeon should imagine a fracture and ignore a dislocation would seem natural to a jury impressed by the dislocated ankle admittedly before the Court and the fact that it would render the plaintiff lame for life. The reasons making such an error highly improbable, together with the full import of the patient's own interference and the comparative weight of the evidence of surgeons of varying degrees of professional eminence and opportunities for forming their opinions are, on the other hand matters far more likely to be properly considered and dealt with by a judge The judge also can reserve his decision and deliver it without haste, after the eloquence of counsel has been to some extent forgotten basing it upon a minute and thoughtful study of the evidence. It must be remembered that however fully the judge may grasp the points of a case and however clearly he may indicate the right course to a jury he may still be unable to overcome prejudices and to guide a verdict. A jury may even seek to show its British independence by going against the recommendation of the judge who in his desire to secure justice for a suitor has to exercise the nicest tact and the most ingenious methods of persuasion in order to avoid if possible, rousing suspicion and opposition and so defeating his own object.

An action tried before Mr Justice CHANNELL and a special jury at the recent assizes at Nottingham suggests many points of interest to medical men which we cannot discuss in detail without a fuller report of the evidence than we have at present seen. It appears however to have been decided upon evidence in many respects closely resembling that given in the Canadian case which we have just discussed.

The action was based upon the alleged negligent and unskilful treatment of the plaintiff by the defendant, a medical man. The injury was a dislocation of the elbow which the defendant, a surgeon, said that he had reduced, not immediately on account of the swelling, but after an interval of some days. He further stated that he had discovered that the elbow was again dislocated several weeks later, when he sent the plaintiff to the Nottingham General Hospital whence he found his way to Charing Cross Hospital There was medical evidence that the defendant should, in the opinion of the witness, have been able to diagnose and to reduce the dislocation at once. There was also evidence that while under the care of the defendant the plaintiff visited two local "bone setters" who presumably handled the elbow, for they stated that at that time the joint was dislocated. For the fair trial of a case such as this, involving as it does the weighing of scientific evidence and the consideration of matters likely to arouse prejudice, a jury, even a special jury, is not necessarily the best possible tribunal. We are not in a position to criticise the verdict in this particular instance, but we may point out that the amount awarded, £25, is a curious sum. If the plaintiff, a collier, was either permanently or for some considerable time (the accident took place in November, 1900) disabled from following his employment, it seems hardly enough, on the other hand, if the disablement was not due to the malpraxis of the defendant the plaintiff was not entitled to any damages at all We refer to the case because in many of its features it is exactly the sort of case where the decision of a sound and strong judge might have been more satisfactory than the verdict of a jury

Annotations.

"Ne quid nimis"

THE HEALTH OF THE KING

WE are glad to announce that the health of the King continues to progress favourably in every direction. Sir Frederick Treves and Sir Francis Laking, who with Surgeon Bankart, R.N, are on board H.M.Y *Victoria and Albert*, are, as will have been seen from the bulletins, able to report that their illustrious patient is doing well in all respects. We may add that the wound is granulating nicely and every precaution is taken to ensure rest to the parts The King still keeps strictly to the recumbent position and has not yet left his couch He is moved from his bed to the couch daily and is wheeled on deck when the weather permits The report that we are now able to give should entirely reassure those who have been a little apprehensive as to the comforts and value of sojourn on board a yacht during the spell of nasty weather with which last week closed and under which this week opened. The complete rest of body and mind which the King is now enjoying will be of the greatest service to his physique.

EXPERIMENTAL PSYCHOLOGY AT KING'S COLLEGE, LONDON

PSYCHOLOGY is now a subject which admits of practical laboratory work, but very few of our universities and colleges have instituted practical departments for the study of this important branch of science. The council of King's College, London, has shown itself abreast of the times by providing a new laboratory for experimental psychology, and Mr W G Smith, M A., Ph D, has been appointed lecturer on the subject The new laboratory will be in contiguity to the physiological laboratory and will be under Dr W D Halliburton's general supervision. Dr Smith is already well known for his work in connexion with the subject at Leipsic and Harvard and more recently for that which he has carried out in the laboratory of the Claybury Asylum in *coöperation with Dr Mott*

HENRY MEMBURY WAKLEY

WE regret to announce the death of Mr Henry Membury Wakley, which occurred on Friday, July 18th Mr Henry Wakley was the second son of Thomas Wakley, M P, coroner for West Middlesex and Founder of THE LANCET, and was born in Brompton in 1824, the year after the first issue of this journal. His second name was that of the village in Devonshire, Membury, from which his father came For some two years he studied medicine at University College Hospital but the work was not congenial to him and subsequently he became a barrister and was for a tim
secretary to the New Equitable Life Assuranc Let
pany, a company which came into existence situated
his father's ideal of a life assurance office the outside

MEDICAL FEES IN CRIMIN *t* for June a full

IN a leading article in THE LANCET gment delivered,
p 85, we dealt at some length with the Hon W G
to medical witnesses in criminal cases, Bench, Ontario
to a scale fixed in 1858, and we illust ly with the facts
reference to a case which recently occ
this case certain medical men refuse law applicable to
girl, said to have been indecently assa in connexion with
that the fees which would be paid to in the Canadian
evidence at assizes or quarter sessions The action was
being thus invited to give would be wholl dical men
to compensate them for the loss of time hey had
entailed There was, we need hardly say no for
of rendering medical aid to an injured per
simply a question of evidence as to whether the that
genital organs had been tampered with We o red
that Mr Justice Kennedy when the attitude her
medical men in this matter was brought to his
expressed a full appreciation of their position, and it will
seen also from a report which we publish at p 237 that t
magistrates of the district, under the chairmanship of Mr Rider Haggard, fully understood the point raised and made a practical suggestion to remedy the difficulty that has arisen. A temperate and well reasoned article in the *East Anglian Daily Times* shows that the medical men in question enjoy the sympathy of their neighbours while it endorses the views of the magistrates—namely, that the proper course is to appoint a medical man to act for the police in all such matters It is obvious that a man who undertakes the duties of a police surgeon, knowing that he will have to make such examinations as those referred to, with the liability to give evidence as a consequence,

places himself by his own act in the position that he occupies, whereas the ordinary medical witness in a criminal case is the victim of circumstances It will be seen however from the report of the proceedings before the Bungay magistrates that the question raised as to expert evidence has been referred to the Home Secretary by the East Suffolk police, and we would call our readers attention to the answers returned. Mr Ritchie differs from Mr Justice Kennedy and we may fairly say from the report quoted that the views of Mr Ritchie do not coincide with those held by the magistrates. Mr Ritchie thinks that 'such refusals must be considered as very discreditable to the medical men concerned but he is glad to believe that such incidents are very rare" We would like Mr Ritchie to explain why it should be discreditable to a medical man to decline to make an examination of a healthy girl s vagina because she has brought an accusation against someone of which he knows nothing when he is aware, perhaps from bitter experience, that his examination may entail his spending a wholly uncertain period at an assize town in return for a fee of a guinea a day with half a crown a night towards his hotel bill, should he incur one. For this is usua a day he will have to leave his patients, making newspape rangements he can for their welfare, and he to make those arrangements in complete un papers curiou to the length of his enforced absence. of verdicts whi tinues the Home Secretary are, as a rule, against if it w to undertake an examination of this sort, judges in JACK t they will only be paid their expenses as to said, however is the expert evidence of Mr Ritchie on a truthfully and t to which we should like to know what his have been. The perfect willingness of are many cases such circumstances is a condition new to passionate or mo while their expenses as witnesses sug parties and an a tchie would expect them to give evidence malpraxis) comes railway fares and the *2s 6d* a night In England, how for their hotel bills But Mr Ritchie ly to propose In an exceptional are referring to n to the refusal of a medical man not aware that hi examination there might be danger blame him for d carriage of justice, you should com likely to find in the Director of Public Prosecutions left to the discret essary employ an expert to make the parties to try the the exceptional nature of the case and carriage of justice, "serious or other on which we are co ised Mr Ritchie does not suggest, but states that he tried rather charge the Imperial Exchequer having consented t iously would be considerable for the fees thoroughly good the expert" supplied by the Public

In this ca han revise a scale of payments arranged had with a century ago and permit medical witnesses recently numerated from the county fund with some gentlem o their loss and the anxiety inflicted upon them of the expression very discreditable by the Home the pr ry is amazing for it is wholly inapplicable to circum and h which no fair minded man can hold to be discredit- treat at all and we regret that there is not in the Home be cretary s letter evidence of that careful consideration of terial facts that should precede official pronouncements, articularly those purporting to convey serious censure of individuals or of a class.

THE METROPOLITAN WATER-SUPPLY

THE report of the condition of the Metropolitan water supply during the month of May has been published recently The Water Examiner states that the Thames water was in good condition at Hampton, Molesey and Sunbury during the whole of the month and that the average daily supply delivered *from the river was 124 094 946 gallons* which is nearly 60 per cent. of the total amount distributed by the London water companies. From the Lee the average quantity abstracted daily was 36,338,271 gallons, and from springs and wells 47 916,315 gallons The total daily quantity was 208,378 583 gallons (including 29 051 gallons daily from the Hampstead and Highgate ponds) for a population estimated at 6 362,684 and this represents a daily consumption per head of 32 75 gallons. In the case of every company the number of gallons supplied per head was less during the month than it was during the corresponding month of the previous year The Chelsea, East London, Grand Junction, and West Middlesex companies now profess to give constant service to all their customers. In the case of the other companies—the Kent New River Southwark, and Vauxhall and Lambeth—constant supplies are respectively given to 98 4 95 93 1 and 76·7 per cent. of the customers. The water supplied by the New River Company was of very good quality The East London Company distributed water which on the average, was of rather better quality than that supplied by four of the Thames companies. A considerable proportion of the water of the East London Company is now obtained from wells. The daily average supply which amounted to 38 790 000 gallons, was made up as follows from the Lee and storage 14 595,269 gallons, from the Thames, 8 174 000 gallons from wells, 10 251 731 gallons, from Hanworth Springs, 1,659 000 gallons, from the Thames, per Southwark and Vauxhall Company," 4 110 000 gallons The water of ' Hanworth Springs" is in reality well water so that the total proportion of well water obtained by the East London Company amounts to little less than one-third of the total supply Samples of the water of all the companies were taken on May 21st and a complete analysis was made of them by Dr T E. Thorpe, F R.S the chemist to the Local Government Board. He found that the relative amount of organic impurity in these samples was represented numerically as follows. Kent and New River 18 Chelsea 24 Lambeth 27, Southwark and Vauxhall and East London, 28 Grand Junction, 29 West Middlesex, 31. The proportion of brown tint seen in samples in a two-foot tube ranged from 3 degrees to 19 degrees of the standard in use. The water of the Lambeth Company exhibited the deepest average shade of brown. The most important results of Dr Thorpe s examination are given in the appended table which shows the results of the analysis expressed in parts per 100 000

BARON LARREY

THERE are few names more honoured not only in France but throughout the civilised world than that of Jean Dominique Larrey—the virtuous Larrey as the great Napoleon called him. In his native country three statues have been erected in his honour and now a fourth monument has appeared in the form of an octavo volume of 756 pages[1] by Dr Paul Triaire. Having had access to many unpublished official and private documents including some collected with filial care by Baron Hippolyte Larrey, the author was afforded an opportunity of producing an exhaustive work and has conscientiously and efficiently performed his task. The book which he has produced is one to be read from cover to cover Larrey's long and strenuous career receives full justice, while incidentally matter of great interest concerning the notable characters and the historical scenes with which he was associated is constantly introduced. "Drawn in the footsteps of the conqueror throughout his vertiginous course," says Dr Triaire in his exordium, "Larrey filled an important place in the Napoleonic epic. He was present on every battle field, and established his ambulances in all the capitals of Europe. In this long and glorious series of campaigns, in this marvellous and dramatic triumphal march when the armies of France advanced from the Nile to the Danube, from Austerlitz to Madrid, from Wagram to Moscow, and from Leipzig to Waterloo, the figure of this army surgeon emerges, stands forth in surprising relief by the side of those of warriors whom a hundred victories have consecrated A character is revealed wherein science, authority, valour, and humanity are combined in a degree never seen before, and probably never to be seen again. In spite of a defective organisation, Larrey contrived single handed to raise the medical service to a level with the rest of Napoleon's army By the side of the machine made perfect for conquest and for death he placed another equally perfect but designed to succour and to preserve From the inferior and discredited rank wherein, notwithstanding their talents, their good service, and their personal sacrifices, the members of the healing art were subordinated in old time armies he raised himself to the level of the most illustrious captains and of the most celebrated physicians From the one class he borrowed talent and intrepidity and from the other science and devotion, thus in his own person uniting the virtues of both" Baron Larrey studied medicine at Toulouse and on graduating entered the French navy In 1793 he was transferred to the army, and in 1797 he joined Napoleon in Italy In 1805 he was placed at the head of the medico surgical department and soon afterwards was created a baron of the empire

A SLANDER CASE

In a leading article in our present issue we venture to suggest that a jury, the vaunted Palladium of British liberty, is not always the most just and satisfactory tribunal for the decision of issues where scientific questions and the interests of medical men are involved. An action tried last June at the assizes at Bury St. Edmunds aptly illustrates our point. The plaintiff Mr A. H Gibbon, medical officer of health of the borough, practising in partnership with Dr R E Nix, the public vaccinator in the same locality, sued a member of the town council for words uttered with reference to himself and his action in recommending certain precautionary measures during the recent outbreak of small pox. The words complained of were, "It is all d——d rot. It is only a got up job on the part of Gibbon and Nix to put money into their pockets for vaccination fees" It was denied that the defendant had used these words and the evidence on the subject was conflicting, but Mr Justice Kennedy told the jury in plain terms that if they found that the defendant did in fact use them there could be no doubt that they were grossly slanderous. To this proposition we should have thought all reasonable men would assent and the point involved in it is one tolerably simple and easy to be grasped If the words were used, as there was no shadow of an attempt to justify their use, it was right that the speaker should be made liable to pay reasonable but not vindictive damages. The jury, however, found that the slander had been uttered, that damages were due to the medical man slandered, and assessed them at one farthing, for which sum judgment was given with costs Such a verdict may well cause fair-minded men to endorse the opinion of Chief Justice Falconbridge[1] upon the defects of the jury system exhibited in actions where prejudice is involved and in particular where medical men are concerned

ARMY ESTIMATES VOTE FOR MEDICAL ESTABLISHMENT

A large portion of the debate in the House of Commons last week on the Army Estimates was taken up with the case of Sir Redvers Buller and relatively little time, considering the importance of the subject, was given to that on the vote of £1,025,000 for the medical establishment We are always glad to see attention called to the army medical service, but it is unfortunate that discussions in the House regarding that service are so frequently unsatisfactory reading to those actually acquainted with the facts and regulations It is confessedly a subject about which but few people have sufficient knowledge to enable them to speak competently and with effect. It is, no doubt, a far more difficult and tiresome process to acquire an up-to date knowledge of official ways and regulations than to sum up the whole matter as the antiquated red tape notions of permanent officials, but general statements and criticism of this sort are very ineffective and do not tend to carry us much "forrader" With regard to the supplies of hospitals and stores for the sick and wounded we are all in favour of simplifying methods of administration and procedure in war and of reducing to the utmost practicable extent the clerical work of medical officers, and we look to Mr Brodrick to see that this is done There are in this and several other directions many desirable changes and improvements which we make no doubt could be carried out if they were properly set about on commonsense lines Concerning these the views of medical officers —who are, after all, most concerned—should be obtained Mr Brodrick should avoid a repetition of the great mistake that occurred in the constitution of the committee for the reorganisation of the medical services—namely, the omission to have upon it an experienced medical officer of high rank. It must always be borne in mind that an army medical officer is called upon by the constitution and terms of his service to discharge a number of duties other than those of a purely professional kind and such as do not fall to the lot of a practitioner in civil life It is only right to add, however, that, speaking generally, we quite concur in what Dr Farquharson said in the debate in question Mr Brodrick and his advisers, if they have not altogether gone on the lines that we suggested or carried out all that we have desired, have nevertheless made many radical and needful changes and introduced many very important and valuable improvements in the army medical service. Mr Brodrick pointed to the fact that there were between 70 and 80 candidates for the 32 vacancies in the Royal Army Medical Corps We are very glad to hear it and hope that the new measures which, taken as a whole, are very good and in the right direction will continue to attract a high class of candidates from the medical schools

THE SUTURING OF HEART WOUNDS

Dr. Harry M Sherman of San Francisco recently delivered an address before the American Medical Association on the Closing of Wounds of the Heart by means of Sutures We have referred to this address elsewhere (p 226) and have analysed the main points of the operation, but some surgeons may desire to have the particulars of

CASES OF SUTURES OF WOUNDS OF THE HEART *

No	Operator and year	Location of external wound.	Chamber wounded and size of wound.	Time of operation after injury	Anæsthetic.	Results and remarks
1	Farina, 1896.	Just above the margin of the left sixth rib near the sternum	Right ventricle, one quarter of an inch; three stitches	—	—	Death on sixth day from broncho-pneumonia.
2	Cappelen 1896	Fourth left intercostal space in mid axillary line.	Left ventricle, four fifths of an inch.	One hour	—	Death after several days; pericarditis; branch coronary artery cut
3	Rehn 1896.	Fourth left intercostal space near the sternum.	Right ventricle three stitches	*The following evening*	—	*Recovery*; empyema.
4	Parozzani 1897	Seventh left intercostal space in the mid-axillary line	Left ventricle, three-quarters of an inch.	Five hours.	None.	Recovery
5	Parozzani.	Third left intercostal space	Left ventricle, three fifths of an inch.	Half an hour		Death on second day from anæmia (?) Interventricular septum had been cut.
6	Fummi 1896.	Under the left nipple.	Apex; cavity not opened; one stitch.	Several hours.	—	Recovery; empyema.
7	Ninni 1898.	Fifth left intercostal space	Left ventricle; three stitches.	Quickly	None	Death on the table
8	Parlavecchio 1896.	"	Left ventricle, one and a half inches; apex.	Eight hours.	Chloroform.	Recovery
9	Giordano, 1898.	Second left intercostal space.	Left auricle, four-fifths of an inch; four stitches.	Half an hour	None	Death on nineteenth day from empyema; abscesses of the right lung
10	Nicholai 1899	Fourth left intercostal space midway between the margin of the sternum and the nipple	Right ventricle	One and a half hours.	Yes	Death after 12 hours
11	*Tuzzi*	*Fourth left intercostal space.*	*Two wounds non penetrating*	—	None.	Death on the twenty second day from empyema; pericarditis.
12	Longo.	Fifth left intercostal space, two-fifths of an inch internal to the nipple.	Left ventricle; three stitches.	At once.		Death in 15 minutes.
13	Ramoni	At third left cartilage, four fifths of an inch from the sternum	Right ventricle; two wounds; one non penetrating four stitches	—		Recovery
14	Marion 1899	Shot through the breast.	Right ventricle; catgut suture.	—	—	Death
15	Rosa, 1899.	Fifth intercostal space.	Left ventricle, three-fifths of an inch; not certain it penetrated ventricle.	—	None.	Recovery
16	Horodynski 1899	—	Right ventricle one and a half centimetres long	—	—	Death
17	Maliszewski 1899	—	—	—	—	"
18	Maliszewski 1899	—	—	—	—	
19	Bufnoir 1899	Sixth left intercostal space.	Right ventricle gunshot 22 calibre.	—	—	Death; necropsy showed perforation of ventricle and the anterior opening only had been sutured
20	Pagenstecher 1899	Fourth left intercostal space beneath the nipple.	Left ventricle, near the apex; two stitches	16 hours	None	Recovery
21	Nanu, 1900	Third intercostal space, four centimetres from the edge of the sternum	Right ventricle, two centimetres long; two interrupted sutures	—	—	Death on the fifth day from infection of the pericardium and pleura.
22	Maselli 1900	Below and internal to the left nipple, cutting the sixth rib	Left ventricle, near the apex; two stitches	One and a half hours	—	Death in 12 hours.
23	Fontan 1900	Six wounds with scissors between the third and the seventh ribs in the cardiac region	Left ventricle 12 millimetres long continuous catgut sutures; three stitches	Six hours	Chloroform	Recovery.
24	Nietert 1901.	—	Right ventricle penetrated; three silk sutures	—	—	Death after 36 hours
25	Vaughan 1901	Fifth left costal cartilage divided	Left ventricle two and a half centimetres long; continuous silk sutures seven stitches	Three-quarters of an hour	Ether	Death on the table from hæmorrhage about completion of operation
26	Nietert, 1901	Left of the sternum.	Left ventricle not sure cavity was penetrated; two sutures	—	—	Recovery
27	Ninni 1901.		Right auricle	—	—	Death in four days *sepsis*
28	Mignon et Sieur 1901	—	Right ventricle	—	—	Death
29	Fontan 1901	—	Left ventricle; catgut sutures.	—	—	Recovered; had empyema.
30	Brenner † 1901	Left of the sternum, near the sixth cartilage.	Right ventricle seven centimetres	The following day	Yes	Death on the table; degenerate heart muscle
31	Watten,‡ 1901	Fourth right intercostal space.	Right ventricle 3·5 to 4 centimetres	—	—	Recovery; right pleura wounded; *pneumothorax*
32	Lastaria, 1901.	—	Left ventricle.	—	—	Died soon.
33	Launay § 1902.	—	Left ventricle, anterior and posterior walls; pistol shot catgut suture in each	—	—	Recovery; no complications
34	Nietert ‖ 1902.	Left sixth interspace, to the right of the papillary line	Left ventricle far back two centimetres; penetration uncertain; two interrupted silk sutures	14½ hours	—	Recovery; purulo-sanguinolent effusion and thoracotomy

collected with filial care by Baron Hippolyte Larrey, the author was afforded an opportunity of producing an exhaustive work and has conscientiously and efficiently performed his task. The book which he has produced is one to be read from cover to cover. Larrey's long and strenuous career receives full justice, while incidentally matter of great interest concerning the notable characters and the historical scenes with which he was associated is constantly introduced. "Drawn in the footsteps of the conqueror throughout his vertiginous course," says Dr Triaire in his exordium, "Larrey filled an important place in the Napoleonic epic. He was present on every battle field, and established his ambulances in all the capitals of Europe. In this long and glorious series of campaigns, in this marvellous and dramatic triumphal march when the armies of France advanced from the Nile to the Danube, from Austerlitz to Madrid, from Wagram to Moscow, and from Leipzig to Waterloo, the figure of this army surgeon emerges, stands forth in surprising relief by the side of those of warriors whom a hundred victories have consecrated. A character is revealed wherein science, authority, valour, and humanity are combined in a degree never seen before, and probably never to be seen again. In spite of a defective organisation, Larrey contrived single handed to raise the medical service to a level with the rest of Napoleon's army. By the side of the machine made perfect for conquest and for death he placed another equally perfect but designed to succour and to preserve. From the inferior and discredited rank wherein, notwithstanding their talents, their good service, and their personal sacrifices, the members of the healing art were subordinated in old time armies he raised himself to the level of the most illustrious captains and of the most celebrated physicians. From the one class he borrowed talent and intrepidity and from the other science and devotion, thus in his own person uniting the virtues of both." Baron Larrey studied medicine at Toulouse and on graduating entered the French navy. In 1793 he was transferred to the army, and in 1797 he joined Napoleon in Italy. In 1805 he was placed at the head of the medico surgical department and soon afterwards was created a baron of the empire.

A SLANDER CASE

In a leading article in our present issue we venture to suggest that a jury, the vaunted Palladium of British liberty, is not always the most just and satisfactory tribunal for the decision of issues where scientific questions and the interests of medical men are involved. An action tried last June at the assizes at Bury St. Edmunds aptly illustrates our point. The plaintiff, Mr A. H Gibbon, medical officer of health of the borough, practising in partnership with Dr R E Nix, the public vaccinator in the same locality, sued a member of the town council for words uttered with reference to himself and his action in recommending certain precautionary measures during the recent outbreak of small pox. The words complained of were, "It is all d——d rot. It is only a got up job on the part of Gibbon and Nix to put money into their pockets for vaccination fees." It was denied that the defendant had used these words and the evidence on the subject was conflicting, but Mr Justice Kennedy told the jury in plain terms that if they found that the defendant did in fact use them there could be no doubt that they were grossly slanderous. To this proposition we should have thought all reasonable men would assent and the point involved in it is one tolerably simple and easy to be grasped. If the words were used, as there was no shadow of an attempt to justify their use, it was right that the speaker should be made liable to pay reasonable but not vindictive damages. The jury, however, found that the slander had been uttered, that damages were due to the medical man slandered, and assessed them at one farthing, for which sum judgment was given with costs. Such a verdict may well cause fair-minded men to endorse the opinion of Chief Justice Falconbridge[1] upon the defects of the jury system exhibited in actions where prejudice is involved and in particular where medical men are concerned.

ARMY ESTIMATES VOTE FOR MEDICAL ESTABLISHMENT

A LARGE portion of the debate in the House of Commons last week on the Army Estimates was taken up with the case of Sir Redvers Buller and relatively little time, considering the importance of the subject, was given to that on the vote of £1,025,000 for the medical establishment. We are always glad to see attention called to the army medical service, but it is unfortunate that discussions in the House regarding that service are so frequently unsatisfactory reading to those actually acquainted with the facts and regulations. It is confessedly a subject about which but few people have sufficient knowledge to enable them to speak competently and with effect. It is, no doubt, a far more difficult and tiresome process to acquire an up to date knowledge of official ways and regulations than to sum up the whole matter as the antiquated red tape notions of permanent officials, but general statements and criticism of this sort are very ineffective and do not tend to carry us much "forrader." With regard to the supplies of hospitals and stores for the sick and wounded we are all in favour of simplifying methods of administration and procedure in war and of reducing to the utmost practicable extent the clerical work of medical officers, and we look to Mr Brodrick to see that this is done. There are in this and several other directions many desirable changes and improvements which we make no doubt could be carried out if they were properly set about on commonsense lines. Concerning these the views of medical officers—who are, after all, most concerned—should be obtained. Mr Brodrick should avoid a repetition of the great mistake that occurred in the constitution of the committee for the reorganisation of the medical services—namely, the omission to have upon it an experienced medical officer of high rank. It must always be borne in mind that an army medical officer is called upon by the constitution and terms of his service to discharge a number of duties other than those of a purely professional kind and such as do not fall to the lot of a practitioner in civil life. It is only right to add, however, that, speaking generally, we quite concur in what Dr Farquharson said in the debate in question. Mr Brodrick and his advisers, if they have not altogether gone on the lines that we suggested or carried out all that we have desired, have nevertheless made many radical and needful changes and introduced many very important and valuable improvements in the army medical service. Mr Brodrick pointed to the fact that there were between 70 and 80 candidates for the 32 vacancies in the Royal Army Medical Corps. We are very glad to hear it and hope that the new measures which, taken as a whole, are very good and in the right direction will continue to attract a high class of candidates from the medical schools.

THE SUTURING OF HEART WOUNDS

DR. HARRY M SHERMAN of San Francisco recently delivered an address before the American Medical Association on the Closing of Wounds of the Heart by means of Sutures. We have referred to this address elsewhere (p 226) and have analysed the main points of the operation, but some surgeons may desire to have the particulars of

CASES OF SUTURES OF WOUNDS OF THE HEART *

No.	Operator and year	Location of external wound	Chamber wounded and size of wound	Time of operation after injury	Anæsthetic	Results and remarks
1	Farina 1896.	Just above the margin of the left sixth rib near the sternum	Right ventricle, one quarter of an inch; three stitches	—	—	Death on sixth day from broncho-pneumonia.
2	Cappelen 1896.	Fourth left intercostal space in mid-axillary line	Left ventricle, four-fifths of an inch	One hour	—	Death after several days; pericarditis; branch coronary artery cut.
3	Rehn 1896	Fourth left intercostal space near the sternum	Right ventricle three stitches	The following evening	—	Recovery; empyema.
4	Parozzani, 1897	Seventh left intercostal space in the mid-axillary line	Left ventricle three-quarters of an inch.	Five hours	None.	Recovery
5	Parozzani	Third left intercostal space	Left ventricle, three fifths of an inch	Half an hour		Death on second day from anæmia (?) Interventricular septum had been cut
6	Fummi 1893.	Under the left nipple.	Apex; cavity not opened; one stitch	Several hours.	—	Recovery; empyema.
7	Ninni 1898.	Fifth left intercostal space	Left ventricle; three stitches.	Quickly	None	Death on the table
8	Parlavecchio 1893.		Left ventricle one and a half inches; apex.	Eight hours.	Chloroform	Recovery
9	Giordano, 1898.	Second left intercostal space.	Left auricle, four fifths of an inch; four stitches.	Half an hour	None	Death on nineteenth day from empyema; abscess of the right lung
10	Nicholai 1899	Fourth left intercostal space midway between the margin of the sternum and the nipple	Right ventricle.	One and a half hours.	Yes.	Death after 12 hours
11	Tuzzi	Fourth left intercostal space.	Two wounds non penetrating	—	None	Death on the twenty second day from empyema; pericarditis
12	Longo	Fifth left intercostal space, two-fifths of an inch internal to the nipple.	Left ventricle; three stitches.	At once		Death in 15 minutes
13	Ramoni	At third left cartilage, four fifths of an inch from the sternum	Right ventricle two wounds; one non-penetrating; four stitches.	—		Recovery
14	Marion 1899	Shot through the breast.	Right ventricle; catgut suture.	—	—	Death
15	Rosa, 1899	Fifth intercostal space	Left ventricle, three-fifths of an inch; not certain it penetrated ventricle.	—	None	Recovery
16	Horodynski 1899	—	Right ventricle one and a half centimetres long	—	—	Death
17	Maliszewski, 1899	—	—	—	—	
18	Maliszewski, 1899	—	—	—	—	
19	Dufnoir 1899	Sixth left intercostal space.	Right ventricle gunshot 22 calibre	—	—	Death; necropsy showed perforation of ventricle and the anterior opening only had been sutured
20	Pagenstecher 1899	Fourth left intercostal space beneath the nipple.	Left ventricle near the apex two stitches	16 hours	None	Recovery
21	Nanu, 1900	Third intercostal space, four centimetres from the edge of the sternum	Right ventricle two centimetres long; two interrupted sutures.	—	—	Death on the fifth day from infection of the pericardium and pleura
22	Maselli 1900	Below and internal to the *left nipple, cutting the* sixth rib	Left ventricle, near the apex; *two stitches*	One and a *half hours.*	—	Death in 12 hours
23	Fontan 1900	Six wounds with scissors between the third and the seventh ribs in the cardiac region	Left ventricle, 12 millimetres long; continuous catgut sutures; three stitches.	Six hours	Chloroform	Recovery
24	Nietert 1901.	—	Right ventricle penetrated; three silk sutures	—	—	Death after 36 hours
25	Vaughan 1901.	Fifth left costal cartilage divided	Left ventricle two and a half centimetres long; continuous silk sutures seven stitches	Three-quarters of an hour	Ether	Death on the table from hæmorrhage about completion of operation
26	Nietert 1901	Left of the sternum.	Left ventricle, not sure cavity was penetrated; two sutures	—	—	Recovery
27	Ninni 1901		Right auricle	—	—	Death in four days; sepsis.
28	Mignon et Sieur 1901	—	Right ventricl	—	—	Death
29	Fontan 1901	—	Left ventricle; catgut sutures.	—	—	Recovered; had empyema
30	Brenner † 1901	Left of the sternum near the sixth cartilage	Right ventricle, seven centimetres	The following day	Yes.	Death on the table; degenerate heart muscle
31	Watten,‡ 1901	Fourth right intercostal space	Right ventricle 3·5 to 4 centimetres	—	—	Recovery; right pleura wounded; pneumothorax
32	Lastaria, 1901	—	Left ventricle	—	—	Died soon.
33	Launay § 1902.	—	Left ventricle anterior and posterior walls; pistol shot; catgut suture in each	—	—	Recovery; no complications.
34	Kletert,∥ 1902.	Left sixth interspace to the right of the papillary line	Left ventricle far back, two centimetres; penetration uncertain; two interrupted silk sutures	1½ hours.	—	Recovery; purulo-sanguinolent effusion and thoracotomy

* Cases 1 to 26 inclusive from table of Dr. Geo. T Vaughan Philadelphia Medical News Dec 7th 1901 † Wiener Klinische Wochenschrift, 1901, No. 11 ‡ Deutsche Medicinische Wochenschrift 1901 No. 37 § La Presse Medical March 29th 1902. ∥ Philadelphia Medical Journal May 3rd 1902.

use two pins are bent into the form of retractors and kept in position by tapes or one pin may be so fashioned as to maintain the patency of the tracheal wound and similarly secured by tapes, and (5) as a drainage tube The ends of the hair-pin are bent outwards to prevent it from slipping into the wound and the rounded end is passed in If two are used with their planes at right angles the wound will be kept more open. It is obvious that the same results can be attained by the use of any piece of wire, but hair-pins may be available when no other form of wire can be obtained.

THE PREVALENCE OF SMALL-POX

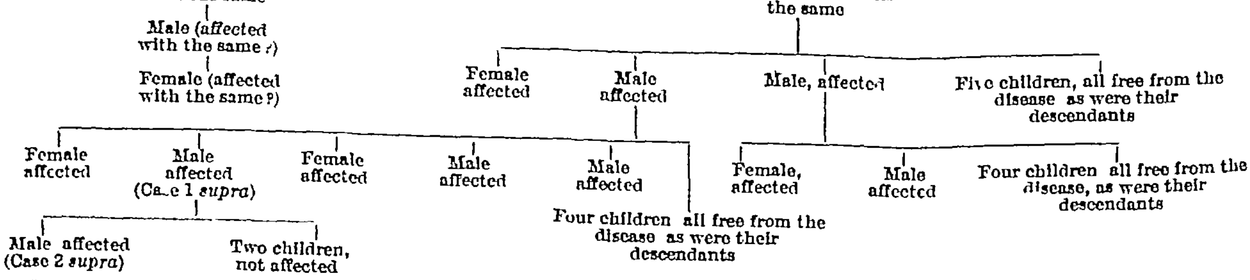
THE following figures show the number of patients admitted to the various hospitals of the Metropolitan Asylums Board for the dates mentioned on Saturday, July 19th, there were 2 fresh cases, on Sunday, the 20th, there was 1 fresh case, on Monday, the 21st, there were 5 fresh cases, on Tuesday, the 22nd, there were 6 fresh cases, and on Wednesday, the 23rd, there were 2 fresh cases

THE SOCIETY OF MEDICAL PHONOGRAPHERS

THIS society will hold its next annual shorthand examination early in May, 1903 Two prizes will be offered, each of the value of £5, one for first-year students and one for students of more than one year's standing The competition will be open to any registered medical student in the United Kingdom who has not taken a first prize at one of the society's previous examinations It will be held simultaneously in London, Edinburgh, Dublin, and at any provincial medical centre in the United Kingdom at which not fewer than three candidates shall offer themselves Intending candidates should send in their names as early as possible to Dr P G Griffith, Bonhams, Farnborough, Hants, who will furnish them in return with a detailed prospectus of the examination The latest date for receiving entries will be April 15th, 1903

THE HEREDITARY NATURE OF SPASTIC SPINAL PARALYSIS 14 CASES IN FIVE GENERATIONS OF A FAMILY

THE separate existence of spastic paralysis of spinal as distinguished from cerebral origin is still doubted, but the hereditary and familial nature of the affection is acknowledged by all In some families the cerebral type seems to occur in certain members (Bernhardt) and the spinal type in others, and in recent years various cases of the disease have been reported by Strümpell, Erb, and others. In the *Philadelphia Medical Journal* of June 21st last, Professor William G Spiller of the University of Pennsylvania reports a remarkable instance which illustrates the hereditary and familial nature of spastic spinal paralysis—viz, its occurrence in 14 individuals belonging to five generations of a family The following is the genealogical table —



Female, slightly affected with spinal spastic paralysis
Female affected with the same
Male (affected with the same ?)
Female (affected with the same ?)
Male affected with the same
Female affected
Male affected
Male, affected
Five children, all free from the disease as were their descendants
Female affected
Male affected (Case 1 supra)
Female affected
Male affected
Male affected
Four children all free from the disease as were their descendants
Female, affected
Male affected
Four children all free from the disease, as were their descendants
Male affected (Case 2 supra)
Two children, not affected

Two of the 14 cases were observed by Professor Spiller and the following is a brief report of each case Case 1.—The patient was a man, aged 32 years, by occupation a telegraph operator He was able to walk with difficulty owing to the prevalence of spinal spastic paralysis of hereditary origin. Both legs exhibited contractures and the left foot was in a position of equino-varus. The knee jerks were exaggerated on both sides Case 2.—The patient, a boy aged eight years, was the son of the above man He suffered from spinal spastic paralysis and talipes equino varus His mother is a healthy woman and has borne two other children who seem to be free from any traces of the disease. A study of the genealogical table will serve to show that the disease is more liable to be transmitted from the parents to the elder than to the younger children of a family

THE BAKERS' SUNDAY REST

IT is always satisfactory to find workmen and their employers working in hearty coöperation for a common and beneficent purpose A circular has been forwarded to us announcing that the London Master Bakers' Protection Society and the Amalgamated Union of Operative Bakers are making united efforts to maintain and to enforce the law of 1822 which prohibits the baking and delivery of bread on Sundays It might be justly conceived that it is the business of the Government to enforce the laws of the land, but we know too well that this is only an ideal conception Laws are enacted but no machinery is instituted to insure their application This notably was the case with the Act of 1822 on bakeries and consequently the law is now openly violated. The bakers themselves have had to institute proceedings and have already spent upwards of £1000 in endeavouring to enforce the Sunday's rest But it is difficult to produce evidence against the offenders, the proceedings against them are costly, and the magistrates interpret the law differently, suspect the prosecutors of interested motives, and only inflict small fines when they do not pronounce an acquitment. From the health point of view there can be no doubt that one day's rest in the seven is an imperative necessity, particularly in trades that are often conducted under unwholesome conditions This is the case in bakeries. The fumes, notably of sulphur, escaping into the bakehouse or cellar from the oven have a marked effect upon the health of the journeyman bakers This is demonstrated by the fact that the statistics of the societies giving sick allowances show that tall men employed in the trade are more frequently on the sick list than are men of shorter stature It is in the upper part of the bakehouses that the fumes accumulate, and the taller the man working there the more impure is the air he breathes Such considerations emphasise the necessity of at least one day's complete rest in the week. On this point there is no division of opinion. But there are differences in regard to the day to be selected for rest. The Jew bakers—and they are numerous—want to rest on the

Saturday and the chief offenders against the law are members of the Jewish community or else such bakers as cater for the wealthy classes As however the vast majority of the inhabitants of this country agree that Sunday should be the day of rest it is urged that the minority must conform to this custom From the practical point of view there is much to be said in favour of this contention, for it greatly simplifies the task of inspection. But from the health point of view all that is needed is the strict observance of one day's complete rest in the seven and if the Jews desire to select Saturday for that purpose it is only in keeping with the modern spirit of religious toleration to allow them to have their own way even at the risk of creating denominational bakehouses. Perhaps a compromise might be possible. A law is always better enforced when all parties concerned approve of the law and we believe that the Jews would assent to compulsory rest on the Saturday In any case rest there must be and we hope that the Home Secretary who has been asked to receive a deputation on this subject, will see his way to realise this principle

THE ETIOLOGY AND PATHOLOGY OF GRAVES'S DISEASE

PROFESSOR CHARLES DANA of New York contributes an interesting article to the *New York Medical Journal* of June 14th last which throws some light on the vexed question as to whether exophthalmic goitre or Graves's disease is a neurosis or a glandular disorder associated with hyper secretion of the thyroid gland. Professor Dana concludes that the primary seat of the disease is in the nervous centres concerned with the innervation of the thyroid gland. An etiological factor the importance of which has been recognised only recently—viz. infection—also plays says Professor Dana a part in the production of the disease. Thus a study of reported cases will show striking instances of Graves's disease following upon fevers sepsis operative procedures, and pregnancies. In his own experience Professor Dana has seen three cases of exophthalmic goitre which developed after typhoid fever One of the curious and instructive facts connected with the pathology of this disease is according to Professor Dana, that in its acute fatal forms the nervous centres in the medulla oblongata or bulb seem to be exhausted and even paralysed. Of interest too are the changes found in the bulbar nuclei in old cases of the disease. Both these facts are shown in the following two cases the second of which also illustrates the very rare incident of embolism in Graves's disease In the first case the patient was a woman aged 23 years who was admitted to the Bellevue Hospital with severe headache and nausea. Inquiry showed nothing of importance in the family history She was of nervous temperament but had been well generally with the exception that for the six years preceding her admission to hospital she suffered from occasional fainting spells but no convulsions The symptoms of headache and nausea were attended with attacks of vomiting She was found on examination to be quite anæmic and there were distinct exophthalmos and enlargement of the thyroid gland especially of its right lobe The carotids were unduly pulsatile and a thrill could be felt over the gland. The pulse was rapid and varied from 90 to 108 (tachycardia) and the respirations were 26 per minute. The temperature was 99·5 F The left ventricle of the heart was somewhat enlarged and there was an intense anæmic murmur at the apex. The liver the kidneys and the urine were normal Her nervousness now increased tremors at first slight, now became frequent and distressing and the tachycardia became more pronounced. On the seventeenth day after admission she passed into a stuporous condition and was unable to swallow food or to talk distinctly There were also a slight ptosis of the left eyelid and other symptoms which led to the belief that there was some lesion of the pons. The pulse-beats increased in frequency and the temperature rose to 107° death occurring on the nineteenth day The post-mortem examination disclosed a normal condition of the heart, the lungs, the kidneys and of the other organs with the exception of the brain and the thyroid. The left crus cerebri was the seat of softening, but there was no hæmorrhage, and the sections showed that the lesion must have been due to thrombosis or embolism The blood vessels showed no evidence of atheroma or of syphilis. The second case was that of a woman aged 45 years with typical symptoms of Graves's disease terminating fatally four months and one week after admission to hospital The necropsy disclosed in this case striking degenerative changes in the bulbar nuclei of the hypoglossal pneumogastric, and other nerves in the form of pigmentation and vacuolation of the cell bodies and a moderate degree of chromatolysis or loss of the Nissl granules of the nerve-cells. The foregoing histories show adds Professor Dana that Graves's disease at times runs an acute course and that in cases of some duration decided changes are found in the nerve-cells of the pneumogastric the hypoglossal, and other nerves within the bulb.

THE death is announced on July 21st, of Dr Carl Gerhardt He died on his estate of Damberg in Baden. Dr Gerhardt was a well known authority on diseases of the lungs and on diseases of children. He was one of those who attended the Crown Prince of Germany afterwards the Emperor Frederick in his fatal illness He it was who discovered the laryngeal growth early in March 1887 He was the editor of A Handbook of Children's Diseases by various writers which was published at Tübingen in 1877 his own contribution being an article on Abdominal Typhoid.

THE BUNGAY MEDICAL PRACTITIONERS AND THE HOME OFFICE

WE have already commented[1] upon the situation produced by the action of the medical men in the district of Bungay Suffolk refusing to examine a child stated to have been indecently assaulted on the ground that the fees for medical witnesses were totally inadequate At the opening of the Bungay petty sessional court on July 17th (there being present Mr H. Rider Haggard in the chair Mr C. G Kemball, and Mr R C Mann) the matter was carried a stage further

Superintendent ANDREWS handed to the Chairman a letter

The CHAIRMAN asked if the Chief Constable wished that the letter should be read from the bench and on Superintendent Andrews answering that this was so, said The matter is this. Some two months ago a case came before this bench of criminal assault upon a child named Alice Jefferies by a man named Howes. In the course of the evidence that was offered it appeared that the child had not been examined by any medical man in the town because the medical men to whom application was made refused to carry out an examination Ultimately the case was committed for trial it went to trial and I believe that the man was convicted The police communicated with the authorities upon the matter of the refusal of the medical men to examine the child The authorities appear to have communicated with the Home Secretary and the Home Office has written a letter to the Chief Constable of East Suffolk who has now formally requested me to read this letter in court I need hardly say that this bench has nothing to do with the question at issue between the medical men and the Home Office The business of this bench in the question is only to try to arrange that the course of justice shall not be interfered with in future in any such cases that may be brought before it The letter is as follows:—

Whitehall, 17th June 1902.

SIR,—In reply to your letter of the 17th ultimo respecting the refusal of certain medical men to examine a child alleged to have been indecently assaulted on the ground that if called as witnesses in a criminal prosecution their remuneration would be insufficient I am directed by the Secretary of State to say that there is no means of compelling a doctor to make the examination. Such refusal as those all the cases which have been published up to the present, we therefore give the accompanying table

---

[1] THE LANCET July 12th p 85

CHEMICAL QUALIFICATION IN IRELAND

AN important step has been decided upon by the council of the Institute of Chemistry by which chemists in Ireland may present themselves for examination in Dublin. Persons thus desirous of qualifying themselves to be public and technical analysts may attend the examinations at the laboratories of the Royal University of Ireland, Dublin The next intermediate and final examinations in Ireland of the Institute will be held in July, 1903

SHOULD THE GOUTY DRINK CIDER?

A BEVERAGE for the gouty relatively harmless and yet containing a small percentage of alcohol is one for which a large number of sufferers from gout would be very grateful, and the medical practitioner is frequently asked if cider is permissible in this respect. The best test of the suitability or otherwise of any beverage for those of arthritic tendencies, either inherited or acquired, is that of experience—i e., as to whether it produces in such subjects an attack of articular gout or other gouty manifestations, and in many cases this test is a very delicate one, any indulgence being frequently followed by some disturbance recognisable both by the patient and the practitioner as the result. Judged by this standard it may be stated that, though as a general rule the gouty are better without alcoholic liquors, yet ordinary "rough" cider, fully fermented and free from sugar, is practically harmless, having little or no tendency to excite an attack of gout. The percentage of alcohol is small and the acidity is chiefly due to malic acid, which is in the body converted into alkaline carbonates and excreted as such, and cider has not therefore the injurious effects in gout of the sweet and highly alcoholic wines On the other hand, partially fermented "sweet cider" or the artificially sweetened and aerated variety, "champagne cider," may excite gouty manifestations in those liable or predisposed to the disease, and should therefore be prohibited Unfortunately the rough cider is to most people less palatable than the sweet variety and especially to the gouty who are in many cases fond of sweet foods and beverages

THE ASSOCIATION FOR PROMOTING THE COMPULSORY REGISTRATION OF MIDWIVES

THE annual meeting of the Association for Promoting Compulsory Registration of Midwives was held on July 22nd at 3, Grosvenor place, London, S W Sir Michael Foster, M P, in seconding the motion for the adoption of the report and balance sheet took the opportunity of accentuating the triumph which those belonging to his school of thinking have obtained over the very large proportion of the medical profession who hold opposite views. Sir Michael Foster declared that it was a great privilege to congratulate the members of the association on their well earned success when they had had to contend against a very considerable section of the medical profession For that very reason we think that Sir Michael Foster might have been a little more thoughtful about the future, perhaps the considerable section will be justified in their opinion It is true that he allowed that there were dangers in connexion with the midwives, and he considered that the members of that association would be doing good service by continuing their organisation and devoting their efforts towards securing that the women for whom they had been working so long should deserve the measure passed on their behalf—and here he was more or less anticipating Dr F H Champneys, the obstetric physician of St. Bartholomew's Hospital, said that the association had now to show that there was no ground of apprehension in regard to all the horrors predicted from what was called the new class of practitioners He was thankful to think that there was a prospect of a body being formed which would overlook the midwives and in a few years' time he believed that the proper limits of a midwife's duty would be settled to general satisfaction Perhaps, but it is probable that neither Sir Michael Foster nor Dr Champneys knows much about the way in which the new Act is likely to operate in rural districts

THE DISTRIBUTION OF PLAGUE

THE weekly return of the Director-General of the Sanitary Department in Egypt shows that for the week ending July 13th there were 5 new cases admitted, 2 of which occurred in Europeans The deaths numbered 6, the recoveries 2, and 9 cases remained under treatment. With respect to sanitary measures, 17,455 rooms were disinfected and 533 were lime washed 119 sacks of effects were disinfected and 7530 sacks of rubbish were burnt. The number of rats killed and burned was 1093

THE ANTI-MEDICAL BIAS

Le Temps, a journal hitherto noted for its temperance of utterance and sanity of outlook, has recently devoted considerable space to the discussion of a work said to have created a *furore* on the continent. The book in question is entitled "Mémoires d'un Médecin," by "Dr Veressaïef"—not by Dumas *pere*—which in 1900 ran serially in the pages of the *Mir Bogyi*, one of the leading St Petersburg reviews. It has been translated into French and into German, and the acute critics of the one nation and the philosophers of the other are said to have acclaimed it To the innate conservatism, or to the honour, of England shall we attribute the fact that an English translation is not yet forthcoming? The work of "Dr Veressaïef," whose real name is Vincent Szmidowicz, is apparently an outcome of the latest development of that dislike of the medical profession which is world old and world wide The writer, we are informed, is the son of an austere, old fashioned practitioner, an adherent of the "vitalist" theories of the early nineteenth century, a devout religionist and severe disciplinarian—in fact, a Russian Puritan and faddist—and to this parent he is said to owe a certain grave moral attitude towards all medical questions He has suffered, moreover, for his opinions. Hence, perhaps, much of the bias of his book, which passes in review a score or more grievances against the profession, well known, *mutatis mutandis*, to all students of the history of society and of medicine, but apparently startlingly novel to the quidnuncs who now dabble in science as once they did in æsthetics The career of a Russian medical student is described and we are informed that a hospital course in Russia convinces the aspirant to a degree of several unpleasant truths—(1) that patients are unduly fatigued by staff and students alike, (2) that the modesty of women is unduly, nay, cruelly, wounded by the same persons, and (3) that the poor are made to pay very dearly for the care bestowed upon them in the wards Dr Szmidowicz has for seven years been attached to a large St. Petersburg hospital devoted to the working classes, but his words would be more convincing were it not possible to parallel them in what we may term medical folklore. It has long been a truism among our own poor who benefit by hospitals that they are experimented upon in those institutions, where they are the *corpora vilia* of teachers and learners alike. This complaint is generally baseless, but it should act as a gloss on the gravamen of the Russian writer The notion that the modesty of women is wounded is as old as the day when throughout Europe the male obstetrician was decried by a generation as little able as its successors to grasp the elementary notion that science views nudity in a purely impersonal light. The ancient doubt in the *bona fides* of medicine justifiable enough in pre-scientific times, lingers unreasonably in the pages of this last exponent of what might be termed *Aerztenhasse* doctor hatred" on the analogy of *Judenhasse* He implies that medicine and surgery are utterly careless of life because many common operations—in Russia at least—have fatal results. Medical innovations, he avers, according to *Le Temps*, are often rather poisons than remedies, and medicine in its present stage knows and can achieve scarcely anything in the direction of positive science The terrible indictment culminates in the enumeration of scores of experiments in serum therapy undertaken upon human subjects by well known men of science in a spirit we seem to be invited to regard as little short of ghoulish. The tirade would be appalling were it not so familiar The writer in fact, belongs to the same category as the anti vivisectionists, the anti vaccinationists the people who ' do not believe in doctors and physic." Only he is more brilliant and better informed in error

THE ASSOCIATION OF BRITISH POSTAL MEDICAL OFFICERS

THE annual dinner of the Association of British Postal Medical Officers was held at the Whitehall Rooms of the Hôtel Métropole, London, on Thursday July 17th Dr J Walton Browne, the President, being in the chair The occasion was honoured by the presence of the Marquess of Londonderry K G, His Majesty's Postmaster General, and a large number of guests distinguished in various walks in life so much so that, perhaps, there was an absence of the usual distinctly medical tone. The meeting at any rate formed an example of the influence which the medical profession and its various branches can bring to bear on the world at large, while it served to emphasise the regret that must be felt that medical men do not unite to make their public value more freely felt than it is. (It might have been thought that things were improving somewhat in this direction but we are afraid that we cannot hope for much real improvement when we find only some 120 medical men assembling to record their votes on such a serious occasion as a change of the constitution of the British Medical Association with its many thousand members.) However on the present occasion there can be no doubt that the British postal medical officers attracted a brilliant company to their banquet which was of a most pleasant nature. The Postmaster General said kind things about Mr Henniker Heaton which Mr Henniker Heaton courteously reciprocated. Sir John Leng M P made friendly remarks about Sir George Murray K.C B the secretary of the Post Office, and Sir George Murray in an able speech promised Sir John Leng that he would keep him to his word In the course of the toast list a presentation consisting of five handsome bowls was made to the energetic and courteous honorary general secretary of the association Dr R. Ritchie Giddings. The presentation was made by the President and suitably acknowledged by Dr Giddings. Other toasts were The Houses of Parliament," proposed by Sir Robert Hunter (solicitor to the Post Office) and replied to by Mr Edward Bond, M P and Mr Joseph Walton, M P Our Colonies, proposed by Sir Hugh Gilzean Reid LL.D and replied to by Sir William Mulock K.C.M G (Postmaster-General of Canada) Sir Walter Peace K.C.M G (Agent General for Natal Colony) and Mr W G Hamilton (Postmaster-General of Transvaal Colony) were also announced to reply but other engagements had unfortunately called them away before owing to the great length of the proceedings the toast was reached. ' The Association of British Postal Medical Officers was proposed by Sir James Crichton Browne and acknowledged by the President; and finally "The Guests given by Dr. R. Paramore, was responded to by Sir Dyce Duckworth. The Imperial Quintette played a good selection of music during the dinner and some excellent songs admirably rendered by Miss Elsie Mackenzie, Miss Ethel Bevans and Mr Herbert Emlyn added much to the enjoyment of the evening's proceedings which did not finish until past midnight this leads us to remark that the only fault we have to find with the executive authorities of the Association is that they are inclined to be even a little too kind to their guests.

THE SURGICAL USES OF THE HAIR-PIN

IN cases of emergency especially in country districts an operation may be necessary and some of the requisite instruments may not be at hand Articles of domestic use can sometimes be adapted and used as substitutes in a manner that the uninitiated would never imagine. The subject has not received the attention from surgical writers that its practical importance demands. Our transatlantic brethren with their great mechanical ingenuity give us some valuable hints. In *American Medicine* of April 5th Dr J Torrance Rugh has published a most useful article on the surgical uses of the hair pin. The subject has previously been treated in a more limited manner by Dr Eberson of Tarnow[1] Ubiquity ease of sterilisation, convenient size, and adaptability to any desired shape by bending render the hair pin exceedingly useful If it is japanned or enamelled the covering can easily be removed by heat. The hair pin may be used in three ways—in its natural form straightened and bent or twisted In its natural form it may be used —1. To pin on dressings or bandages (for this purpose the points may be sharpened) 2. To remove concretions or foreign bodies from a sinus or natural canal. The rounded end of the hair pin is passed over the object which is then withdrawn. Professor Horwitz of the Jefferson Medical College has suggested bending the rounded end on the flat to an angle of 10° or 15 which facilitates the removal of a body from a canal such as the urethra. 3. As a blunt curette. Dr Eberson has suggested this use. For the removal of soft granulation tissue or of any softened or broken-down material the hair pin is as useful as any blunt curette If the granulations are deep the hairpin may be used grasped in forceps. 4 As an æsthesiometer The points of the hair pin may be set close or wide and the sensitiveness of the part determined. 5 To catheterise a female The rounded end is passed through the urethra the points being firmly held to prevent the hair pin from slipping into the bladder or better the ends are first bent outwards which renders this accident impossible. 6. To pass under a blood vessel and with a figure-of eight ligature or by compression to arrest hæmorrhage. 7 As a pair of callipers Straightened the hair pin may be used—1 As a probe. Dr Rugh has easily explored Stenson's duct with it to determine the presence of a calculus. 2. To wire bones together in cases of resection and fracture. 3. After sterilisation to rupture the membranes during labour 4 As a small cautery 5 As hare lip pins 6. As a hook to abstract foreign bodies from canals and sinuses. 7 As a tenaculum. Bent or twisted into the required shape the hair pin may be used (1) as a nasal speculum (2) as a retractor for wounds or for the eye lids nose lips and labia (3) as an aneurysm needle, (4) in lieu of a tracheotomy tube—for this most important use two pins are bent into the form of retractors and kept in position by tapes or one pin may be so fashioned as to maintain the patency of the tracheal wound and similarly secured by tapes, and (5) as a drainage-tube. The ends of the hair-pin are bent outwards to prevent it from slipping into the wound and the rounded end is passed in If two are used with their planes at right angles the wound will be kept more open. It is obvious that the same results can be attained by the use of any piece of wire, but hair-pins may be available when no other form of wire can be obtained.

THE PREVALENCE OF SMALL-POX

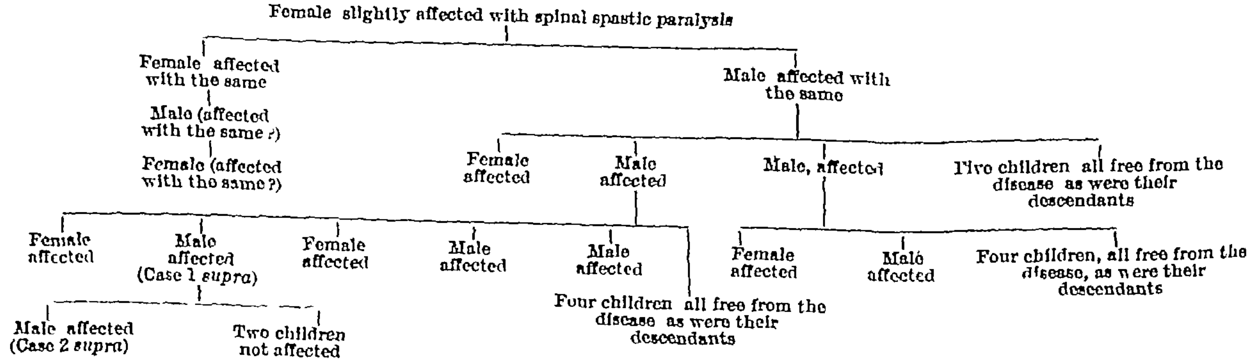
THE following figures show the number of patients admitted to the various hospitals of the Metropolitan Asylums Board for the dates mentioned on Saturday, July 19th, there were 2 fresh cases, on Sunday, the 20th, there was 1 fresh case, on Monday, the 21st, there were 5 fresh cases, on Tuesday, the 22nd, there were 6 fresh cases, and on Wednesday, the 23rd, there were 2 fresh cases

THE SOCIETY OF MEDICAL PHONOGRAPHERS

THIS society will hold its next annual shorthand examination early in May, 1903 Two prizes will be offered, each of the value of £5, one for first-year students and one for students of more than one year's standing The competition will be open to any registered medical student in the United Kingdom who has not taken a first prize at one of the society's previous examinations It will be held simultaneously in London, Edinburgh, Dublin, and at any provincial medical centre in the United Kingdom at which not fewer than three candidates shall offer themselves Intending candidates should send in their names as early as possible to Dr P G Griffith, Bonhams, Farnborough, Hants, who will furnish them in return with a detailed prospectus of the examination The latest date for receiving entries will be April 15th, 1903

THE HEREDITARY NATURE OF SPASTIC SPINAL PARALYSIS 14 CASES IN FIVE GENERATIONS OF A FAMILY

THE separate existence of spastic paralysis of spinal as distinguished from cerebral origin is still doubted, but the hereditary and familial nature of the affection is acknowledged by all In some families the cerebral type seems to occur in certain members (Bernhardt) and the spinal type in others, and in recent years various cases of the disease have been reported by Strümpell, Erb, and others In the *Philadelphia Medical Journal* of June 21st last, Professor William G Spiller of the University of Pennsylvania reports a remarkable instance which illustrates the hereditary and familial nature of spastic spinal paralysis—viz, its occurrence in 14 individuals belonging to five generations of a family The following is the genealogical table —



Female slightly affected with spinal spastic paralysis
Female affected with the same
Male (affected with the same ?)
Female (affected with the same ?)
Male affected with the same
Female affected
Male affected
Male, affected
Five children all free from the disease as were their descendants
Female affected
Male affected (Case 1 supra)
Female affected
Male affected
Male affected
Four children all free from the disease as were their descendants
Female affected
Male affected
Four children, all free from the disease, as were their descendants
Male affected (Case 2 supra)
Two children not affected

Two of the 14 cases were observed by Professor Spiller and the following is a brief report of each case. Case 1.—The patient was a man, aged 32 years, by occupation a telegraph operator He was able to walk with difficulty owing to the prevalence of spinal spastic paralysis of hereditary origin Both legs exhibited contractures and the left foot was in a position of equino-varus The knee jerks were exaggerated on both sides Case 2.—The patient, a boy aged eight years, was the son of the above man He suffered from spinal spastic paralysis and talipes equino-varus His mother is a healthy woman and has borne two other children who seem to be free from any traces of the disease A study of the genealogical table will serve to show that the disease is more liable to be transmitted from the parents to the elder than to the younger children of a family

THE BAKERS' SUNDAY REST

IT is always satisfactory to find workmen and their employers working in hearty coöperation for a common and beneficent purpose A circular has been forwarded to us announcing that the London Master Bakers' Protection Society and the Amalgamated Union of Operative Bakers are making united efforts to maintain and to enforce the law of 1822 which prohibits the baking and delivery of bread on Sundays. It might be justly conceived that it is the business of the Government to enforce the laws of the land, but we know too well that this is only an ideal conception Laws are enacted but no machinery is instituted to insure their application. This notably was the case with the Act of 1822 on bakeries and consequently the law is now openly violated. The bakers themselves have had to institute proceedings and have already spent upwards of £1000 in endeavouring to enforce the Sunday's rest. But it is difficult to produce evidence against the offenders, the proceedings against them are costly, and the magistrates interpret the law differently, suspect the prosecutors of interested motives, and only inflict small fines when they do not pronounce an acquitment From the health point of view there can be no doubt that one day's rest in the seven is an imperative necessity, particularly in trades that are often conducted under unwholesome conditions This is the case in bakeries The fumes, notably of sulphur, escaping into the bakehouse or cellar from the oven have a marked effect upon the health of the journeyman bakers. This is demonstrated by the fact that the statistics of the societies giving sick allowances show that tall men employed in the trade are more frequently on the sick list than are men of shorter stature It is in the upper part of the bakehouses that the fumes accumulate, and the taller the man working there the more impure is the air he breathes Such considerations emphasise the necessity of at least one day's complete rest in the week. On this point there is no division of opinion. But there are differences in regard to the day to be selected for rest. The Jew bakers—and they are numerous—want to rest on the

Saturday and the chief offenders against the law are members of the Jewish community or else such bakers as cater for the wealthy classes. As however, the vast majority of the inhabitants of this country agree that Sunday should be the day of rest it is urged that the minority must conform to this custom. From the practical point of view there is much to be said in favour of this contention, for it greatly simplifies the task of inspection. But from the health point of view all that is needed is the strict observance of one day's complete rest in the seven, and if the Jews desire to select Saturday for that purpose it is only in keeping with the modern spirit of religious toleration to allow them to have their own way even at the risk of creating denominational bakehouses. Perhaps a compromise might be possible. A law is always better enforced when all parties concerned approve of the law and we believe that the Jews would assent to compulsory rest on the Saturday In any case rest there must be and we hope that the Home Secretary who has been asked to receive a deputation on this subject, will see his way to realise this principle.

THE ETIOLOGY AND PATHOLOGY OF GRAVES'S DISEASE

PROFESSOR CHARLES DANA of New York contributes an interesting article to the *New York Medical Journal* of June 14th last which throws some light on the vexed question as to whether exophthalmic goitre, or Graves's disease is a neurosis or a glandular disorder associated with hyper secretion of the thyroid gland. Professor Dana concludes that the primary seat of the disease is in the nervous centres concerned with the innervation of the thyroid gland. An etiological factor the importance of which has been recognised only recently—viz. infection—also plays says Professor Dana a part in the production of the disease Thus a study of reported cases will show striking instances of Graves's disease following upon fevers sepsis operative procedures and pregnancies. In his own experience Professor Dana has seen three cases of exophthalmic goitre which developed after typhoid fever One of the curious and instructive facts connected with the pathology of this disease is, according to Professor Dana that in its acute fatal forms the nervous centres in the medulla oblongata or bulb seem to be exhausted and even paralysed. Of interest too are the changes found in the bulbar nuclei in old cases of the disease. Both these facts are shown in the following two cases the second of which also illustrates the very rare incident of embolism in Graves's disease In the first case the patient was a woman aged 23 years who was admitted to the Bellevue Hospital with severe headache and nausea. Inquiry showed nothing of importance in the family history She was of nervous temperament but had been well generally with the exception that for the six years preceding her admission to hospital she suffered from occasional fainting spells but no convulsions The symptoms of headache and nausea were attended with attacks of vomiting She was found on examination to be quite anæmic and there were distinct exophthalmos and enlargement of the thyroid gland especially of its right lobe. The carotids were unduly pulsatile and a thrill could be felt over the gland The pulse was rapid and varied from 90 to 108 (tachycardia) and the respirations were 26 per minute. The temperature was 99·6 F The left ventricle of the heart was somewhat enlarged and there was an intense anæmic murmur at the apex. The liver the kidneys and the urine were normal. Her nervousness now increased tremors, at first slight, now became frequent and distressing and the tachycardia became more pronounced. On the seventeenth day after admission she passed into a stuporous condition and was unable to swallow food or to talk distinctly There were also a slight ptosis of the left eyelid and other symptoms which led to the belief that there was some lesion of the pons. The pulse-beats increased in frequency and the temperature rose to 107° death occurring on the nineteenth day The post-mortem examination disclosed a normal condition of the heart, the lungs, the kidneys and of the other organs with the exception of the brain and the thyroid. The left crus cerebri was the seat of softening but there was no hæmorrhage, and the sections showed that the lesion must have been due to thrombosis or embolism. The blood vessels showed no evidence of atheroma or of syphilis. The second case was that of a woman aged 45 years with typical symptoms of Graves's disease, terminating fatally four months and one week after admission to hospital The necropsy disclosed in this case striking degenerative changes in the bulbar nuclei of the hypoglossal pneumogastric, and other nerves in the form of pigmentation and vacuolation of the cell bodies and a moderate degree of chromatolysis or loss of the Nissl granules of the nerve-cells. The foregoing histories show adds Professor Dana, that Graves's disease at times runs an acute course and that in cases of some duration decided changes are found in the nerve-cells of the pneumogastric, the hypoglossal, and other nerves within the bulb.

THE death is announced on July 21st, of Dr Carl Gerhardt He died on his estate of Damberg in Baden. Dr Gerhardt was a well known authority on diseases of the lungs and on diseases of children. He was one of those who attended the Crown Prince of Germany afterwards the Emperor Frederick in his fatal illness. He it was who discovered the laryngeal growth early in March, 1887 He was the editor of A Handbook of Children's Diseases, by various writers which was published at Tübingen in 1877 his own contribution being an article on Abdominal Typhoid.

THE BUNGAY MEDICAL PRACTITIONERS AND THE HOME OFFICE

WE have already commented[1] upon the situation produced by the action of the medical men in the district of Bungay Suffolk refusing to examine a child stated to have been indecently assaulted on the ground that the fees for medical witnesses were totally inadequate At the opening of the Bungay petty sessional court on July 17th (there being present Mr H. Rider Haggard in the chair Mr C. G Kemball and Mr R C Mann) the matter was carried a stage further

Superintendent ANDREWS handed to the Chairman a letter

The CHAIRMAN asked if the Chief Constable wished that the letter should be read from the bench and on Superintendent Andrews answering that this was so said The matter is this. Some two months ago a case came before this bench of criminal assault upon a child named Alice Jefferies by a man named Howes In the course of the evidence that was offered it appeared that the child had not been examined by any medical man in the town because the medical men to whom application was made refused to carry out an examination Ultimately the case was committed for trial; it went to trial and I believe that the man was convicted. The police communicated with the authorities upon the matter of the refusal of the medical men to examine the child. The authorities appear to have communicated with the Home Secretary and the Home Office has written a letter to the Chief Constable of East Suffolk who has now formally requested me to read this letter in court I need hardly say that this bench has nothing to do with the question at issue between the medical men and the Home Office The business of this bench in the question is only to try to arrange that the course of justice shall not be interfered with in future in any such cases that may be brought before it The letter is as follows —

Whitehall 17th June, 1902.

SIR,—In reply to your letter of the 17th ultimo respecting the refusal of certain medical men to examine a child alleged to have been indecently assaulted on the ground that if called as witnesses in a criminal prosecution their remuneration would be insufficient I am directed by the Secretary of State to say that there is no means of compelling a doctor to make the examination. Such refusal is a thor to which your letter refers must, in Mr Ritchie s opinion, be considered as very discreditable to the medical men concerned, but he is glad to believe that such incidents are very rare Doctors are, as a rule perfectly willing to undertake an examination of this sort though aware that they will only be paid their expenses as witnesses

---

[1] THE LANCET July 12th p. 85.

Mr Ritchie would suggest that in an exceptional case where owing to the refusal of a medical man to make such an examination there might be danger of a serious miscarriage of justice you should communicate with the Director of Public Prosecutions who could, if necessary, employ an expert to make the examination

As a general rule however such expenses ought not to be thrown on Imperial funds I am Sir your obedient servant,

Charles S Murdock

The Chief Constable of East Suffolk, Ipswich

The **Chairman** It only remains for the Bench to discover what is the attitude of the medical faculty in this town upon the subject—whether they still decline to deal with such cases or not?

Superintendent **Andrews**: That I am not in a position to say sir I have not conferred with the medical men the matter has been in the hands of Inspector Steggles but I understand from him that they refuse to act in all cases of criminal assault because their remuneration is not sufficient

The **Chairman** Can you ascertain what is the position?

The **Clerk** Mr Tetley is here

The **Chairman** Then Mr Tetley can speak for himself (To Mr Tetley) Do you represent the feeling of the medical men in Bungay?

Mr F H **Tetley**: I am exceedingly obliged to you for allowing me to have the opportunity of hearing this letter read I want it to be plainly understood on behalf of the medical profession in Bungay that the reason we objected to examine this case was as a strong protest against the miserably low fees which are offered to us for attending the quarter sessions or assizes to give evidence The fee we get is a guinea a day and our railway ticket and if detained over one day we get 2*s* 6*d* for our bed I may state also that it is contrary to the ethics of the profession that in any cases where either life or limb is involved or in cases where it is a matter of alleviating human suffering the question of fee or reward scarcely ever—I hope never—enters the mind of a medical man in deciding whether he should give his services or not But in these cases I certainly think that the State should remunerate us better than it does I hope the magistrates do not think that we sprang a mine upon the police in the case referred to for immediately after the case which went from here to the assizes in November last we distinctly told the inspector of police that in future under no conditions whatever until the remuneration was altered would we attend to these sort of cases I may add that it is unfortunate that my colleague Mr G H Ransome is away just now but he is exactly of the same opinion as myself and unless the remuneration is altered we shall decline to examine in any of these cases

The **Chairman**: That is your fixed determination?

Mr **Tetley** Yes and of the medical men in Bungay

Superintendent **Andrews** Is it only the fee allowed for staying over night that you complain of?

Mr **Tetley**: No the fees generally

The **Chairman**: I should like to say that although we have heard from Mr Tetley that the police were given notice in November last that the medical faculty of the town refused to attend these cases of criminal assault and similar cases so far as I am aware I never heard of any such notice The bench knew nothing of it and it therefore came as a surprise to us when this child was brought up unexamined We have listened to what Mr Tetley has said and I again repeat that we have nothing whatever to do with the rights of the matter The question at issue is one for the Home Office to deal with

Mr **Tetley** Mr Chairman could I possibly have a copy of that letter to send to The Lancet? The Lancet is our medical journal and it has taken up the matter

The **Chairman**: The letter having been read here by the request of the police authorities is public property May I make a suggestion? Would it not be possible for a medical man to be appointed for the division to deal with such cases?

Superintendent **Andrews**: I have been thinking the matter over seriously and I feel that the time has arrived when it should be so This matter was duly reported to me by the inspector here and in turn reported by me to my superiors It is, however, a unique case and there was a difficulty in dealing with it But I do think the time has arrived when a medical gentleman should be appointed for each division so far as police matters are concerned

Mr **Tetley** We have been driven to this conclusion by degrees

The **Chairman**: You have raised an important issue which has now got to be settled somehow

Mr **Tetley**: We get no fees from our police cases at all We may be rung up in the middle of the night for a man who may be hanged but we get no fee whatever

Superintendent **Andrews**: That is a matter for the coroner except in cases of paupers when it comes on the parish

Mr **Kimball** You object rather to be taken away from all your work for perhaps two or three days to the county assize (or sessions) at the present remuneration?

Mr **Tetley**: Yes

Superintendent **Andrews** We are in the same position with regard to architects and surveyors whose allowance is but 3*s* 6*d* a day

The **Chairman** (to Superintendent Andrews) Perhaps you will convey to the Chief Constable the suggestion which the bench makes that the Home Office should be communicated with and asked if a medical man could not be appointed for each division The suggestion made by the Home Office that the Director of Public Prosecutions should be communicated with scarcely seems to be adequate because we all know that the delay might mean that any traces of an assault may have vanished by the time that any examination takes place at the instance of the Director of Public Prosecutions

Mr W G Grace, M R C S Eng , L R C P Edin , completed his fifty fourth year on July 18th Lately he has been devoting some attention to the game of bowls and last week he made his 200th three figure score at cricket

THE ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS FOR THE YEAR 1901

PART I REPORTS

Second Notice[1]

One of the most valuable parts of the chief inspector s report is the summary which he gives of the Factory and Workshops Act, 1901 It may be remembered that two Factory Bills were introduced concurrently into the House of Commons Of these two Bills the first was framed with a view to consolidate the then existing Factory Acts of 1878, 1883, 1891, and 1895, and the Cotton Cloth Factories Acts of 1889 and 1896 The second Bill was drawn up to amend the existing law in certain particulars These Bills passed through Committee and received some amendments in the process The provisions of the second Bill were then added to the first Bill which proceeded in the form of a single measure and received the Royal Assent in August, 1901. A very important feature of the new Act is that the question of ventilation can now in many cases for the first time be efficiently dealt with by the factory inspectors In previous Acts provisions had been made in regard to the amount of air space which had to be provided for the workpeople, but there was no statutory provision to insure the supply of fresh air There was a requirement that the temperature of the air should be reasonable, but there was a complete absence of any necessity on the part of the manufacturer to trouble himself about the purity of the air breathed by the workpeople The manufacturer might, therefore, by any means he choose raise the temperature of the air at the expense of its purity This is in fact what actually happened In the case Deane *v* Beach it was proved that the temperature of a room was raised "by heating it with gas jets and stopping up the chimneys " The magistrate before whom the case was tried regretted that he was obliged to dismiss the summons which was taken out under the section of an Act which reads thus "In every factory or workship adequate measures shall be taken for securing and maintaining a reasonable temperature in each room in which any person is employed "[2] It was held on appeal at the High Court of Justice (King's Bench Division) that the magistrate was right in his decision. Mr Justice Ridley held that temperature is clearly not the same thing as ventilation and that the temperature, which in this case was 61° Fahr , was reasonable and Mr Justice Bigham pointed out that a reasonable temperature was the only thing aimed at in the section which was relied on by the prosecution The magistrate who first tried the case gave it as his opinion that "such an abominable and disgraceful state of things should be remedied." The Act of 1901 which has accomplished this reform provides that sufficient ventilation must be maintained to render harmless all gases, vapours, and dust Attention has been already called[3] to the extremely unsatisfactory condition of the ventilation in many of the cotton-weaving sheds, in which the air had been examined by Mr W Williams, the inspector of cotton cloth factories In his introductory summary to the work done by his department, the Chief Inspector hardly gives sufficient prominence to the report on the cotton cloth factories and he omits to refer the reader to the part of the volume in which this report is to be found The space at our disposal will only admit of a brief summary of the work done by the inspector who gives a full account of the investigations which he made in regard to the quality of the air in certain factories and in weaving sheds During the year 1901 13 new cotton cloth factories were worked and there were 12 additional cotton spinning rooms The regulation of the amount of moisture in the air has already been a matter of considerable importance in these factories If the air be too dry the process of weaving cannot be satisfactorily conducted, and if it be too moist the comfort of the workers is interfered with. On this question there were formerly many complaints and until the year 1889 no legal limit was put on the amount of humidity permissible and it was not until that year that hygrometers were generally introduced into these factories. Improvements followed the introduction of these instruments and in 1896 a committee under the chairmanship of Sir Henry Roscoe, made investigations which led to further changes in the law two years later The condition of the workers has generally improved. Mr Williams pays a pleasing tribute to the exertions of some of the large manufacturers who have raised the standard of sanitation and of comfort in their workshops to a higher level than that demanded by the letter of the law They have been rewarded by an improvement in the quality of the work done and by the diminution in the sick rate of their work people. The improvement in the purity of the air in these factories is a direct result of the recommendation of Sir Henry Roscoe's Committee which was enforced first as a regulation and which has now become a statutory provision and is incorporated in the Factory and Workshop Act, 1901.[4] The inspector of cotton cloth factories, in his report for the year 1900 gave a table showing the amount of improvement which had been affected in 35 weaving sheds[5] In the report for the year 1901 he gives figures respecting tests made during the year 1901 in 43 weaving sheds containing an aggregate of about 7000 workers A comparison of this table with the one published in the previous report shows that a further improvement has been effected during the year A table made from the averages of these two sets of cases is given below It shows in the case of 35 sheds in the year 1900 and in the case of 43 sheds in the year 1901 the number of volumes of carbonic acid found in 10 000 volumes of air[6] (1) before the improvement in ventilating arrangements was effected and (2) after the improvement in ventilating arrangements was effected The figures in columns C and D are obtained by deducting from the amount of carbonic acid experimentally found to be present in the workrooms the amount normally present in the outside air of manufacturing towns which is estimated as four volumes per 10 000 The actual improvement effected is perhaps most easily realised by comparing these two columns.

---

Carbonic Acid (CO_2) in Cotton-weaving Sheds

—	Number of volumes of carbonic acid (CO_2) per 10 000 volumes of air		Approximate number of volumes of CO_2 per 10 000 due to respiration	
			C	D
	Before improvement in ventilating arrangements	After improvement in ventilating arrangements	Before improvement in ventilating arrangements	After improvement in ventilating arrangements
For the year 1900, average of 35 cases … … …	13	7·9	9·8	3·9
For the year 1901, average of 43 cases … … …	12·6	7·7	8·6	3·7

The average of the respiratory impurity in the individual samples of air referred to in the table has been reduced to considerably less than one-half of the amount previously found and in some cases there was even a greater improvement than this Considerable improvement undoubtedly has been effected in the health of the workmen through these changes but no statistical details on the question are to be had as there is a general absence of records of sickness amongst weavers. It is however known that in ill ventilated sheds it was a common thing in the summer for the workers to faint and that this has not been the case since the improved conditions of ventilation have been introduced. Workmen say that they now feel less exhausted at the end of their day's work than they had formerly felt at midday Manufacturers are in general agreement that the work has been better done since the operatives have been placed under less unhygienic conditions. The ventilation of certain spinning rooms is still very unsatisfactory and the average length of life of a spinner is said to be shorter than that of a weaver Many of the rooms in which spinning is done are sufficiently large to provide a fairly liberal amount of cubic space for each worker but efficient provision is not made for the supply of fresh air Sometimes it is said that the condition of the external air is too dry for admission into the rooms and that it would, if it were not first warmed and damped, act injuriously on the work. Moreover the air of Lancashire towns is not free from smoke and fog which are prejudicial to fine yarns The impurity of the atmosphere in some of the mills is simply appalling Some statistics were published from the report for the year 1900[7] The following extract is from one of the tables given in the report for 1901, it shows the gross pollution by carbonic acid found in the air of some of the mills

Carbonic Acid (CO_2) in Cotton Spinning Mills
